PREFACE

This book contains a selection of papers accepted for presentation and discussion at the 45th annual conference of the European Society for Engineering Education - SEFI (Société Européenne pour la Formation des Ingénieurs) with the theme "Education Excellence for Sustainable Development" (SEFI 2017).

SEFI is the largest organisation of higher engineering education institutions in Europe, and through its membership it connects over one million students and 160.000 academic staff members in 48 countries. The mission of SEFI is to contribute to the development and improvement of engineering education, to reinforce the position of engineering professionals in society, to improve the dialogue between all the actors of engineering education (policy makers, academic leaders and staff members, students, employers and related partners).

This conference had the support of the Dassault Systemes, MarhWorks, Granta Material Intelligence, National Instruments, Project Management Institute, and Quanser. We also thanks to Governo dos Açores and Câmara Municipal de Angra do Heroísmo.

It took place at Angra do Heroísmo, Terceira Island, Azores, Portugal, during September 19–21, 2017.

The Program Committee of SEFI 2017 was comprised of a multidisciplinary group of experts and those who are intimately concerned with engineering education. They have had the responsibility for evaluating, in a 'blind review' process, the papers received for each of the main themes proposed for the conference: (A) Sustainability and Engineering Education; (B) University-Business cooperation; (C) Engineering Skills; (D) Quality Assurance and Accreditation; (E) Continuing Engineering Education and Lifelong Learning; (F) Open and Online Engineering Education; (G) Ethics in Engineering Education; (H) Curriculum Development; (I) Attractiveness of Engineering Education, (J) Physics and Engineering Education; (K) Mathematics and Engineering Education; (L) Engineering Education Research; and (M) Gender and Diversity.

SEFI 2017 also included workshop sessions taking place in parallel with the conference ones. Workshop sessions covered themes such as: WA1 - Increasing interactivity in lectures; WA2 - Addressing Attrition: Changing Students' Futures: A Problem-Based Workshop; WA3 - Attractiveness of Engineering Profession in Europe; WA4 - The Online Learning HUB: a tool for teachers to develop and run online courses; WA5 - Demonstration of the Engineering

Education Research to Practice Cycle Using a Cyberlearning System for Environmental Education and Research; WA6 - Interdisciplinary Project Management in Engineering Education; WA7 - Closing the gap: Cooperation between secondary schools and Engineering institutions; WA8 - Employability of Engineering Graduates; WA9 - Teach as you preach: Professionalizing teaching assistants in engineering science within the 2020 context; WA10 - Future development of teaching & learning in Engineering Education; and WA11 - Publishing in an engineering education research journal.

SEFI received about 300 contributions from many countries from the 5 continents around the world. The papers accepted for presentation and discussion at the Conference are published by this book and will be submitted for indexing by ISI, Scopus, DBLP and/or Google Scholar, among others.

We acknowledge all that contributed to the staging of SEFI 2017 (authors, committees, workshop organizers, and sponsors). We also would like to thank ISEP (Instituto Superior de Engenharia do Porto). We deeply appreciate their involvement and support that was crucial for the success of SEFI 2017.

Welcome to SEFI 2017

SEFI – European Society for Engineering Education

SEFI is the largest network of higher education institutions (HEIs) and educators in Europe. Created in 1973, SEFI is an international non-profit organization aiming to support, promote, and improve European higher engineering education, enhancing the status of both engineering education and engineering in society.

SEFI is an international forum composed of higher engineering education institutions, academic staff and teachers, students, related associations and companies present in 48 countries. Through its membership and network, SEFI reaches approximately 160.000 academics and 100.000 students. SEFI represents 4 decades of passion, dedication and high expertise in engineering education through actions undertaken according to its values: engagement and responsibility, respect of diversity and different cultures, institutional inclusiveness, multidisciplinary and openness, transparency, sustainability, creativity and professionalism. SEFI formulates ideas and positions engineering education issues, influences engineering education in Europe, acts as a link between its members and European and worldwide bodies, contributes to the recruitment of good students whilst always promoting an international dimension in engineering curricula.

Our activities: Annual conference, ad hoc seminars/workshops organized by our working groups and task forces, specific events and actions for deans in engineering such as the SEFI European Engineering Deans Council (EEDC), scientific publications (incl. European Journal of Engineering Education), European projects, position papers, cooperation with other major European and international bodies such as the European Commission, the UNESCO, the Council of Europe or the OECD. The cooperation with partner and sister organisations in Europe and in the world, is also one of our proud priorities.

Welcome to Azores

Mother nature has created a land full of wonders at Azores. Surrounded by the blue immensity of the Atlantic Ocean, there are nine islands, nine small and wonderful worlds, ready to be explored. The beaches of warm white sand, the volcanic lakes and landscapes are some of the attractions of these place.

Azores are a land full of nature beauty, as well the opportunities. In nowadays, the islands are recognised not only about their speechless scenario, also about the sustainability potentialities. Here the tourism and development are welcome, but in harmony with the environment. More secrets? In these islands, magic is still alive through the friendliness of the inhabitants, and by the delicious food.

Terceira is the second most inhabited island of Azores. Ask us some places to visit and we will give you a never-ending list. At the World Heritage town of *Angra de Heroísmo* you'll find a place immersed in its history and monuments. However, if you feel more passionate about nature there are plenty of options, starting with the vestiges of the volcanic activities, such as the *Algar do Carvão*: a deepen volcanic chimney. The *Furnas do Enxofre* deserves a visit too, among other spectacular places.

At Terceira you'll find history, fun, urbanity, thermal waters, friendly people, outstanding beaches and nature beauty. At the same time, there are whales and dolphins that can be spotted, to the delight of visitors. Be ready to taste a land of unique flavours. Be ready to explore a deep blue sea, to climb the mountains and to expand your horizons.

Welcome to Azores, and enjoy a taste of pure freedom!

Welcome message from *Instituto Superior de Engenharia do Porto*

On behalf of *Instituto Superior de Engenharia do Porto* (ISEP) I am very pleased to welcome you to the 45th annual conference of SEFI – the European Society for Engineering Education. We are proud to host the conference and bring all experts, innovators and educators of engineering education together at Azores.

ISEP is a trademark of engineering education and innovation. Since 1852, we have been pioneering the training and the specialisation of engineers with a strong creative and entrepreneurial mind-set. Our academic community combines ambitious and dynamic people, who believe in the potential of innovation and technology to promote a sustainable development. Over 6500 students and 500 faculty & staff motivated by the promise that engineering moves the world and create opportunities.

The students of ISEP benefit from an excellent learning environment, a prestigious institution and quality infrastructures. By exploring EUR-ACE and CDIO international best practices, we are creating opportunities for students to connect to the real-world and develop academic projects with companies and research groups. In 2017, ISEP has been awarded with more international accreditations. So, we have now 13 EUR-ACE labels and the on M.Sc. with ABET certification in Portugal. These numbers show up the excellence of the engineering education at ISEP.

In fact, ISEP has a strong strategy for the internationalisation, and that's why we have over 100 international partnerships that allow students to enjoy ERASMUS+ mobility. At the same level, ISEP has international agreements with South American and Asian higher education institutions, also double-degree agreements with Brazilian and Spanish institutions and is open to receive people from whole world. We believe in a strong and multicultural community working together for enhancing and explore now the future of the engineering.

"Education Excellence for Sustainability" was chosen as theme of the conference because this matter is very important for all of us, despite where we came from. Furthermore, this theme has a paramount relevance for the Azores islands, because these place is a worldwide reference on the successful sustainability development aligned with the wonderful landscape values.

I hope that during the conference ideas will be exchanged and developed and new models of co-operation created. I wish you all a very pleasant stay in Terceira.

João Rocha,
ISEP President

Keynote speakers and presentations

Dr. Dorte Rich Jørgensen

Principal Sustainability Engineer, Technical Authority Sustainability
Atkins

Dr Jørgensen provides strategic leadership within Atkins and the British construction industry as a sustainability expert and has 28 years' experience of successfully embedding sustainability into the built environment and infrastructure projects on a range of cutting edge and award-winning project such as London 2012 and Chiswick Park, and within large businesses.

Dorte is the former Atkins Infrastructure teams' sustainability manager for the London 2012 Olympic and Paralympic Park project and was sponsored by the institution for eminent engineers, Royal Academy of Engineering, as a Visiting Professor of Innovation at Heriot-Watt University in 2011-2015. Dorte is a founding industry director for the Royal Academy of Engineering's Centre for Excellence in Sustainable Building Design, a network bringing together Britain's leading Universities, creating a network of cross-collaboration between academia, industry and professional institutions. As a thought leader and business professional, Dorte is focussed on driving better collaboration between industry, academia, and industry bodies whilst influencing policy, codes and diversity in Britain at a national level. Dorte is a public speaker and author.

Delivery Excellence for Sustainability on Mega Projects

Delivering sustainability excellence on multi-billion dollar projects requires an on-going learning and growth environment.

The blueprint behind the delivery of major programmes such as London 2012 - the greenest games ever which saw 11,000 project staff at peak - will be presented, with a focus on the outcomes of infrastructure design. In addition, observations will be shared on the knowledge and skills engineering professionals need to enable a sustainable construction industry which is playing its part in addressing climate change and bringing hope for the future.

Dr. Gary Bertoline

Dean & Distinguished Professor of Computer Graphics and Computer & Information Techology
Purdue University

Dr. Gary R. Bertoline is the Dean of the Purdue Polytechnic Institute and a Distinguished Professor of Computer Graphics Technology and Computer & Information Technology at Purdue University. He earned his PhD at The Ohio State University and was on the faculty in the College of Engineering for 3 years before coming to Purdue University in 1990. Gary served as founding Department Head of Computer Graphics Technology then led the creation of the Rosen Center for Advanced Computing and the Envision Center for Perceptualization.

He co-founded the Indiana Next Generation Manufacturing Competitiveness Center (IN-MaC) as well as the Polytechnic Institute initiative at Purdue University. The Polytechnic initiative is a major effort to transform the college's curricula and learning experience for the students to better prepare graduate for life and work in the digital age. He has authored numerous papers in journals and trade publications on engineering and computer graphics, computer-aided design, and visualization research.

He has authored and co-authored seven text books in the areas of computer-aided design and engineering design graphics with one, Fundamentals 3D Solid Modeling and Graphics Communications currently in its 7th edition. Gary's research interests are in scientific visualization, interactive immersive environments, distributed and grid computing, workforce education and STEM education.

Transforming Engineering Technology Higher Education for the Digital Age

There is a long rich history to the development of higher education as it is practiced in most developed countries in the world. Engineering education has a shorter history but sharing the same roots as higher education in general. The original intent of engineering education was to prepare graduates that could become the leaders in the development of the Industrial Age.

Just as the Digital Age has become the catalyst for profound changes in society in general, it is also impacting higher education, specifically engineering education. With the world's knowledge easily and instantaneously accessed through hand-held devices like mobile phones, what might higher education look like in the Digital Age?

At Purdue University we are attempting to answer this question by transforming the learning experience of our students and transforming what it means to be a professor in higher education. This bold initiative is completing its third-year and the transformation of an entire college is beginning to take form.

Dr. Giovanni Azzone

Full Professor
Politecnico di Milano

Born in Milano, 24.11.1962, received his Master of Science, cum laude, in Management Engineering at Politecnico di Milano, in 1986. Since 1994 he is Full professor of Business Economics and Organization at Politecnico di Milano.

He served in many National and International university boards. Specifically, he was: Rector of Politecnico di Milano from 2010 to 2016; President of T.I.M.E. Network (2013-2015); President of Alliance 4 Tech (2016); Member of the Heads Board of Idea League (2016), Member of the Board of Ècole Centrale Paris (2012-14); Vice President of the National Committee for the Evaluation of State Universities (Comitato Nazionale per la Valutazione del Sistema Universitario) of the Ministero dell'Istruzione, Università e Ricerca (2004-2010); Academic Vice President of Unitech, a non-profit organization founded by 8 of the main European Engineering Universities (2002-2006).

He currently is Member of the Swiss Accreditation Council and of SIBAC-Seoul International Business Advisory Council, and Project coordinator for the National Program on Risk Prevention of the Italian Presidency "Casa Italia".

Educating for a changing world: New challenges for Engineering Schools

Over the last few years, many societal changes affected the context where Engineers and Engineering Schools live. A growing need for Environmental sustainability in processes and products, Digitalization of Economy and Society, Globalization, just to consider the most important emerging issues, are affecting the way engineers operate and the way they must be educated and trained.

The lecture will outline the consequences of these changes on the expected output of engineering Schools (i.e., competence and skills required) and their actual input (i.e., the competence and skills of new freshmen), deriving some consequences for the contents and process of engineering education.

Dr. Maria Knutson Wedel

Vice President of Education
Chalmers University

Maria Knutson Wedel is Vice President of education at Chalmers University of Technology and a professor in Engineering Materials (MSc in Engineering Physics, PhD in Physics). She is serving on audit committees for university evaluation for the Norwegian and Danish Agency for Quality Assurance in Education. She is a member of the board of the science centre Universeum and has been deputy director of the Gothenburg Centre for Environment and Sustainability, head of Chalmers mobility programme UNITECH, programme director of the Materials Masters programme and "faculty coach" in sustainable development.

Maria has published more than 60 papers in materials science and educational development and has contributed to the development of the international CDIO initiative. She co-authored the chapter Teaching and Learning in "Rethinking Engineering Education - The CDIO Approach" 2007. She was awarded Wallenberg scholarship 1998-99, Jacob Wallenberg Foundation prize for materials science 2007 and Chalmers pedagogical prize 2009.

The journey of integrating sustainable development in engineering education at Chalmers. Ups, downs, side tracks and vision

Engineering education develops continuously in many aspects and sustainability is one of them. From a focus on mere technology to include environmental effects related to technology, it has turned towards the integration of a contemporary complex definition of sustainability as being the relationship between the three pillars of economical, societal and ecological sustainability. As a part of facing the challenge of that complexity, many universities e.g. develop routes to integrate engineering ethics, to relate educational goals to the seventeen Sustainable Development Goals, or to educate engineering students to address global societal challenges that are multidisciplinary in its nature.

The story from Chalmers of leading and managing change regarding education for sustainable development (ESD) encompasses failed projects as well as working models. The talk will include both failures and models as valuable learning experiences. These hold several questions such as: What do students think about sustainable development courses and why? Why does a teacher not want to be taught? Is transformative learning necessary? What role can companies and society play in education for sustainable development? Chalmers current model to embed sustainable development will be presented including some examples which seem to work today, as well as challenges that are still to be overcome. Additionally, there will be a short reflection regarding the call for skills needed in a future digitized sustainable society.

ABSTRACT

The orientation program MINT^{grün} at Technische Universität Berlin (TU Berlin) offers two study semesters for open choices of teaching modules including a series of specially designed laboratories for research-based learning (RBL).
The online project laboratory in chemistry (OPLChem) offered in MINT^{grün} follows the concepts of RBL with a transdisciplinary approach and allows for a free choice of a project drafted by the students themselves. The concept of the OPLChem seems to motivate the students to follow their interests in sustainability research as during the last two years 16 of 23 student groups chose topics typically related to sustainability. Our students publish their results in the form of videos and blogs in the internet. In this way a growing pool of new blogs and online videos of various experiments was established for the public.

Conference Key Areas: Sustainability and Engineering Education, Open and Online Engineering Education, Attractiveness of Engineering Education

Keywords: research based learning, project laboratory, sustainability research

INTRODUCTION

Topics related to sustainability research motivate students in the initial stage of their studies. The orientation program MINT^{grün} offered as a two semester program at TU Berlin helps students to discover interests before entering a graduation course [1].

Especially during the initial phase of studies there is a lack of student centred learning environments in most STEM courses (German: MINT for Mathematics, Informatics, Nature Sciences and Technics). In contrast to this MINT^{grün} offers nine specially designed, interactive laboratories which cover topics such as robotics, construction, environmental research, mathematics, gender studies and chemistry. The suffix “grün” which means “green” indicates the link to sustainability and is intended to motivate the students´ interest in this area at the initial stage of their studies.

The students choose at least one laboratory where they have an interest to conduct their own project. The topics are often related to contemporary research topics in ecology, sustainability or social and intercultural debates and therefore of high societal interest. In the framework of MINT^{grün} we offered the Online Project Laboratory in Chemistry (OPLChem).

The OPLChem follows the concepts of research-based learning (RBL) with free choice of research topics and a transdisciplinary approach; the latter is a key component of sustainability science [2, 3]. It was reported in literature that free-choose learning and research promotes environmentally sustainable attitudes and behaviour [4].

In recent years students chose 16 out of 23 projects directly related to sustainability research such as the quantification of heavy metals in drinking water, in nutrition supplements, in food and soil; the production and decay of biodegradable plastics, electricity from bacteria, fuel cells, hydrogen from bacteria, photosynthesis research and alternatives for industrial fertilizers.

The concept of the OPLChem further motivates the students by giving them the opportunity to present their results to the public. The students produce online-videos and publish blogs in the internet.

The growing pool of online materials represents another aspect of sustainability as the experimental results are more persistently visible in comparison to the usually written paper protocols that vanish after correction by the supervisors. Videos turn out to be a suitable tool explaining important aspects of the theory, the configuration of complex experimental setups, the basic questions of interest and finally the videos offer a presentation tool for the students [5, 6].

In 2013 Professor Thomas Friedrich was awarded a Fellowship by the Joachim Herz Foundation for excellence in teaching, specifically for the whole teaching concept of the OPLChem. One year later, in 2014, Franz-Josef Schmitt was awarded a Fellowship by the Joachim Herz Foundation for excellence in teaching with regards to the targeted inversion of internships in chemistry, biotransformation and micro economy (IGT-educationTUB).

1. CONCEPT OF RESEARCH-BASED LEARNING AND MINT^{GRÜN}

MINT^{grün} students are school absolvents that just entered university typically aged 18 years or even younger [1,7]. RBL trains skills such as the ability to independently formulate questions and conceive research plans and to take responsibility for the outcome of projects [8]. The connection of orientation studies and RBL seems to be most promising in achieving successful identity, orientation and self-confidence among the students [9,7]. Interestingly it also activates students to choose topics related to sustainability [3]. RBL is additionally well suited for online support and new technologies as part of blended learning concepts [10,11].

2. THE ONLINE PROJECT LABORATORY IN CHEMISTRY (OPLCHEM)

The OPLChem follows the concept of RBL. Team RBL is a very effective way of promoting students' awareness of social, economic and environmental sustainability issues [12]. The introduction period of the OPLChem (see Fig. 1) mainly divides into i) the best practice examples introduced by students from former semesters (as part of their presentation) motivating the students research questions, ii) the investigation period for studying existing literature and collecting information and iii) the conception period combining ideas to an experimental concept, defining methods and considering the setup. Also the necessary materials are identified and organized. Usually the students define their topics within the first 2-3 weeks of the semester and come together in groups ranging from 2-4 participants. Then they conduct their research in the laboratory during the experimental period.

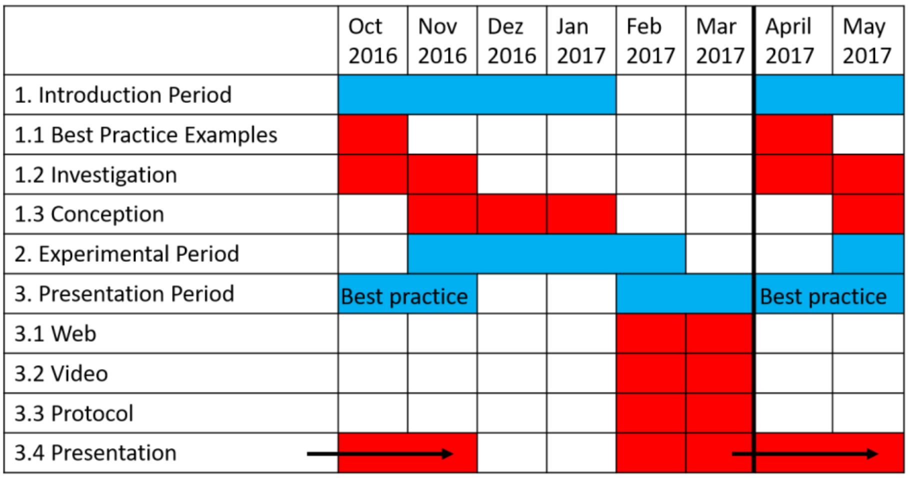

Fig. 1 Structure of the OPLChem in form of a gantt chart

At the end of the course the students have to present a written protocol and produce either a video or a blog where the conducted experiment and the results are described. Usually the video and blog are hosted at YouTube® or Wordpress®, respectively, and therefore public. Their presentations are impulse talks for the next group of students.

Fig. 1 presents the structure of OPLChem and the three overlapping periods which are marked in blue: 1) the introduction period, 2) the experimental period and 3) the presentation period. Marked in red one can see the segmentation of the introduction period and the presentation period. The semester change between March and April is indicated by a black vertical line.

3. RESULTS

During the last winter semester WS 2016/17 38 students participated in the OPLChem. The projects chosen by these students were: 1) oxygen production in photosynthesis, 2) light driven adaption of algae, 3) heavy metals in food supplements, 4) mercury in seafood, 5) gene analysis with polymerase chain reaction, 6) genetically modified organisms, 7) electricity produced by bacteria, 8) biopolymers, 9) generation and photocatalytic activity of nanoparticles, 10) optical properties of different nanoparticles and 11) function of ink erasers.

In recent years an average of about 50 % of all students who had undergone the OPLChem finished their projects with a presentation, written protocol and either video or online blog or both. All blogs as prepared by the students are collected in a metablog which is accessible via the URL http://oplchem.wordpress.com (Fig. 2)

Fig. 2 Metablog subsuming the students´ efforts in the OPLChem

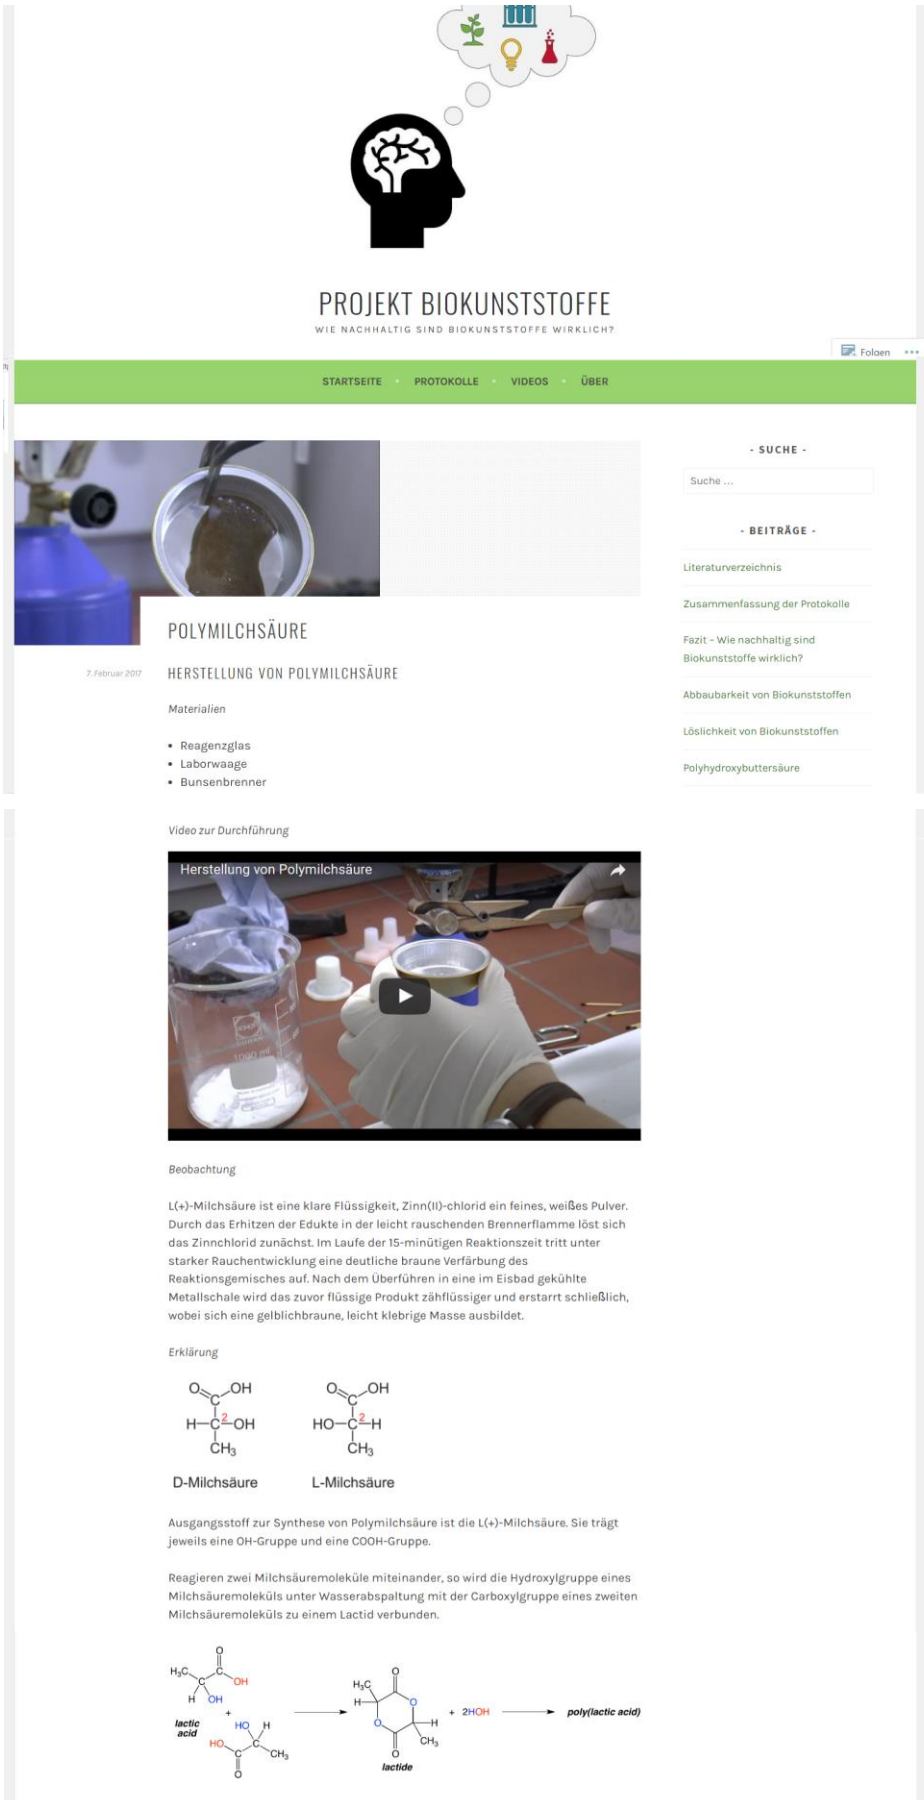

Fig. 3 Screenshot of the blog https://projektbiokunststoff.wordpress.com/

Fig. 3 presents the screenshot of a group that synthesized and investigated a number of various biopolymers such as polylactic acid, polyhydroxybutyrate, galalith or starch. They compared these polymers with industrial biopolymers such as technically produced polylactic acid and the synthetic polymer polyurethane. The degradation in contact to earth and water as well as the solubility in various different solvents was studied. The findings were subsumed in a protocol as well as presented on the blog. For the synthesis of most of the biopolymers a short video was produced and linked to the blog. The students´ presentation and discussion of their project can also be found on the blog.

4. DISCUSSION

The orientation study program MINT^{grün} is very successful regarding the number of participating students. The number of MINT^{grün} students rose from 77 in the first year, to 177 in the second year, to 325 in the third year and has stabilized at around 500 students since 2015. The proportion of women increased from 22% to 34% in the same time. In the winter semester 2015/16 21 students participated in the OPLChem. This number grew to the maximum capacity of 38 places in 2016/17: 28 students from Mint^{grün} and 10 students from Bachelor of Chemistry studied in the OPLChem during the winter semester 2016/17, of which 12 students were women (32 %). About 1/3 of the students from MINT^{grün} in the OPLChem announced an interest in continuing with Bachelor of Chemistry.

In general MINT^{grün} helped a lot of students to choose their future studies whereby most of the students who wanted to study announced that they are interested in STEM (up to 75%) [9].

We assume that for most of the students especially in the early stage of their studies there exists a strong attraction to topics of sustainability and the students appear to be highly motivated in getting engaged in such topics.

The concept of the OPLChem seems to motivate the students as they can follow their interests and have the opportunity to publish their projects in the form of videos and on a blog in the internet. Such online materials are transdisciplinary and sustainable as the students online published experimental results are more persistently visible in comparison to the usually written paper protocols that vanish after correction by the supervisors.

This approach also opened the laboratory for the public and turned out to be an interesting concept to support collaborations as for example with the office for urban development of the government of Berlin.

Interviews with the students showed that especially the groups who had experience with RBL during their school time were quick in finding project ideas or even wanted to proceed with their former school projects.

5. CONCLUSIONS

The main aim of the OPLChem is to introduce students to situations of real laboratory research and they should be motivated for hard working engagement to solve difficult issues in chemistry. This might sound as a contradiction to develop own interests however we believe that RBL can offer both, experience of reality and identification.

It turned out that this concept of RBL is highly appreciated by the students. Especially the flexibility in scheduling the time for the experiments was positively judged.

We believe that the concept of RBL in orientation studies together with transdisciplinarity for example by blended learning elements such as online videos and blogs is highly attractive and motivates sustainability research projects. RBL brings students into contact with the requirements of the subjects on the one hand and gives them freedom to follow own research questions on the other. It allows good students to explore their limits. RBL should ideally include elements which are typical for the subject such as the need to write elaborated and exact protocols as in studies of chemistry, so that the students in MINT^{grün} experience the study reality and get a good orientation from participating in OPLChem. But RBL should also allow for the freedom of a researcher to choose his questions, to design experiments and to schedule his time on his own.

ACKNOWLEDGEMENTS

The authors acknowledge support by TU Berlin in the framework of the student reform project “educationZEN in Praktika”. Special thanks belongs to the board of teaching and studying (LSK) and the board of the faculty (FKR II) who were both engaged in discussions and contributed with constructive criticism to the success of this project and finally decided on the funding in a positive way. The authors thank the Executive Board (President Prof. Christian Thomsen and the Vice President for education Prof. Hans-Ulrich Heiss) from TU Berlin for his support to MINT^{grün}.

Thomas Friedrich and Franz-Josef Schmitt especially thank Stifterverband der Deutschen Wissenschaft and Joachim Herz Stiftung for supporting the projects “Onlineprojektlabor Chemie im Alltag” and “IGT- educationTUB” and support by the ministery of education and research (BMBF) for financing the *WIMI^{plus}* project SynTUBio. Central institute of scientific cooperations (ZEWK) at TU Berlin is acknowledged for supervising *WIMI^{plus}*.

Christian Schröder and Zulehya Yenice Campbell acknowledge support by the ministery of education and research (BMBF) for funding the project MINT^{grün}.

The authors thank Ahmad Aljanazrah from Bierzeit university Palestine for his support and didactic advices.

ABSTRACT

This paper outlines a generic guideline for planning and implementing an action-based and transnational course in higher education for training the engineering competencies required in a future dynamic European workplace and economy. This guidance is intended for universities, research and teaching institutes, as well as for

[1] Corresponding Author

companies interested in establishing novel teaching concepts by closing the gap between know-how and experience. The guideline will provide suggestions and lessons learned for the realization of an efficient and effective implementation. Important development phases of the guideline are explained through a use case based on a master course, which has been jointly established in cooperation by four European universities. Learning objectives for this course aim at raising the awareness about sustainable value creation by focusing on the development of sustainable and technological innovations with entrepreneurial objectives.

Conference Key Areas: Sustainability and Engineering Education, Curriculum Development, Engineering Skills

Keywords: Guideline for Higher Education, Transnational Teaching and Learning, Sustainable Value Creation

INTRODUCTION

The future working environment of young engineers within the dynamic European society and economy will be coined by mobility, intercultural exchange, and virtual cross-border communication. Future engineers will be more and more required to work in international teams and be able to interact effectively and efficiently with colleagues, suppliers, and customers coming from different countries as well as cultural backgrounds. Moreover, modern digital engineering tools are driving this change in a very fast way. As a result, the training of mobility as well as of transnational and intercultural competencies has become a strong requirement for teaching and learning in higher education. To this aim, the paper outlines a guideline for planning and implementing an action-based and transnational course in higher education for training young engineers towards a future dynamic European workplace and economy. It aims to empower organizations to implement their own action-based and transnational activities by providing highly practical-oriented recommendations. This guidance is intended for universities, research and teaching institutes, as well as for companies interested in establishing novel teaching concepts in higher education. The action-based and transnational course addressed within this guideline consists of the following training and teaching phases involving a consortium of international learners and supervisors:

- A project working phase driven by a challenging engineering problem including:
  - International mobility phases for both students and teachers
  - Virtual cooperation and collaboration through digital tools
- E-learning lectures

The paper outlines the methodical background (1) and the state-of-the-art (2) for the action-based and transnational course. The guideline (3) addresses the activities: preparation, development, as well as implementation, evaluation, and follow-up. Important development phases of the guideline are explained on the basis of a use case patterned on the master course “European Engineering Team”. Learning objectives for this course aimed at raising the awareness about sustainable value creation by focusing on the development of sustainable and technological innovations with entrepreneurial objectives. The concept, first results, and outcomes of the course are described in [1] and at the project website (engineering-team.net/).

1 METHODICAL BACKGROUND

The framework for the action-based and transnational course in higher education follows the concept of Experiential Learning, based on the research results from David Kolb [2, 3]. Experiential Learning is based on a learning cycle of reflecting on the impacts of performed activities and subsequently deriving and implementing measures for improving these activities [3]. For combining the learning cycle with the search for solutions during the project work of the course, a specific logic was developed. This logic is an integration of the approaches presented in [3, 4, 5, 6, 7]; it supports the natural problem solving behaviour of humans and originally is inspired by the TOTE-Model [8]. *Fig. 1* shows the logic of the learning cycle applied during the project working phase. Moreover, specific elements have been developed for training different competencies of the learner. The structure of the relevant competencies is oriented on the competence profile for sustainable leadership [9] and consists of four main competencies: professional competence, methodical competence, social competence, and self-competence. *Table 1* points out the relevant course elements for training the four main competencies. For the improvement of the course, different evaluation activities with a subsequent development of improvement measures are carried out. The framework has been implemented and evaluated within the first and second cohort of the European Engineering Team.

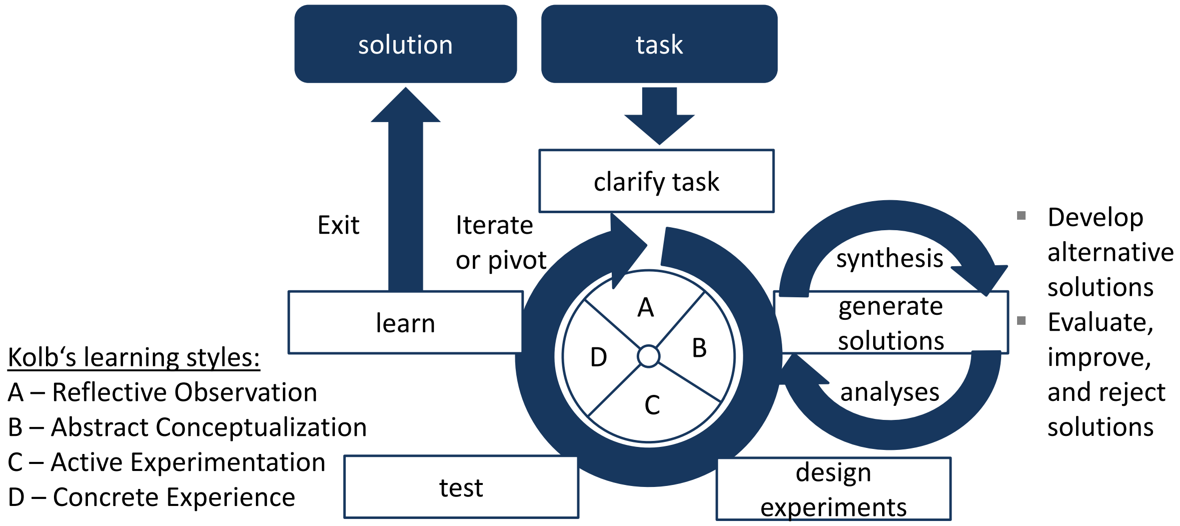

Fig. 1. Learning cycle for the project working phase (in accordance with [10])

Table 1. Course elements for training the competencies

Competencies		**Course Elements**
Professional and methodical competencies	▪ Depending on the involved engineering disciplines	▪ Project topic ▪ E-learning lectures ▪ Application of specific engineering methods and tools depending on the project topic ▪ Application of digital tools for communication
Social competencies	▪ Intercultural competencies ▪ Capacity for team work ▪ Communication capability ▪ Willingness to resolve conflicts ▪ Persuasive strength	▪ Intercultural team composition ▪ Project work in small teams and with work packages ▪ Periodic presentations of the work progress
Self-competencies	▪ Self-confidence and leadership ▪ Mobility and flexibility ▪ Engagement and reliability ▪ Target orientation and commitment	▪ Mobility phases ▪ Intercultural teamwork

2 STATE-OF-THE-ART

The state-of-the-art derives from approaches for action-based and transnational curricula in engineering education, considering both virtual and physical elements. The virtual-oriented approaches put an emphasis on online cooperation between the transnational partner organizations.

- Moore and May describe an interactive online course for engineering students based on a web-platform between the University of Virginia and the Dortmund University [11].
- Petrea and Velescu present an example of a mostly virtual-oriented approach with only one initial meeting for inter-university teaching of science students in a foreign language (French) [12].
- TRIP was a project aimed at using web services for distribution of large software engineering projects [13].
- Teaching students global software engineering skills using distributed Scrum in inter-university Canadian-Finnish teams was described in [14].

The physical-oriented approaches are essentially characterized by short-term, collaborative working phases, which take place with a co-located team and specific tasks and objectives.

- The BASE Transnational Training Course established by Fundação da Faculdade de Ciências da Universidade de Lisboa (FFCUL) and by the Ecologic Institute in Berlin provides a curriculum for the implementation of climate change adaptation projects using hands-on experiments and case studies for 16 learners [15].
- “Global Engineering Teams” managed by Global Education Team UG is an international and interdisciplinary project-oriented study course specifically for engineers [16].
- Jane presented a transnational course prepared by four European universities in the area of construction engineering and management [17]. All the activities were performed during physical meeting. The entire course lasts 28 academic weeks and students reside 9-10 full weeks at three different campuses, respectively.
- Mukerji presents further examples in [18].

The approach presented in this paper integrates both sets of practices and puts the focus on sustainability in entrepreneurial engineering.

3 GUIDELINE

The guideline is one of the final deliverables from an ERASMUS+ strategic partnership project. It captures lessons learned from our experiences as well as practical recommendations for any educational or training consortium interesting in replicating our engineering program. The guideline will be structured in the main activities: preparation (3.1) development (3.2), as well as implementation, evaluation, and follow-up (3.3). These activities are briefly outlined in this paper and are undergoing continuous improvements as we proceed with the ERASMUS+ project. Each activity covers different development phases (A-I) for the action-based and transnational course in higher engineering education. These phases address the development of different course elements.

3.1 Preparation

The definition of the course curriculum is the first relevant phase (A) for initiating the future action-based and transnational teaching and learning activity. This phase follows a fairly typical planning model including the development of the course elements A.1-A.5 It covers the definition of a vision and mission for the course (A.1), as well as an outline of the leaning outcomes (A.2) and learning contents (A.3). This includes a definition of specific competencies for the course as well as a generic description of the applied procedures, principles, methods, and tools. The learning outcomes and learning contents define specific teaching and learning activities against which a duration and workload needs to be subsequently determined (A.4). Lastly, the target group and pre-requisite knowledge of the participants (A.5) are elaborated. For the development of the course elements, it should be ensured that they can be realized by applying the learning cycle in *Fig. 1*.

Within the second phase (B), the necessary stakeholders have to be identified, selected, and first contacts have to be established (B.1). The main relevant stakeholders are the transnational teaching partners from different countries. The partners should be selected according to the different competencies required to realize the learning outcomes as well as the learning contents. Besides, it should be ensured that the curriculum can be adjusted to the individual academic calendars of the partners. Other relevant stakeholders are e.g. external experts or organizations who/which are required for supporting the course with know-how or materials. For establishing the cooperation with the stakeholders, it seems to be more promising to select stakeholders with already existing good contacts on all organizational levels, e.g. from chair, to department, and up to administrative level. All project partners should be involved as early as possible in the development of the course elements. This process was applied by the European Engineering Team, with an early assessment of the feasibility of the course concept and detailed schedule for each university's curriculum and academic calendar. Concurrent to the selection of the stakeholders, a funding for the mobility phases (B.2) and the required materials for the project working phase (B.3) need to be specified.

The alignment of the course schedule to the academic calendars of the partners as well as the establishment of a funding for the course has been experienced as especially critical for the development of the European Engineering Team.

3.2 Development of the course model

After the preparation, the detailed course model has to be elaborated. This covers as a first development phase, the definition of the educational contents (C). The concrete topic for the project working phase (C.1) has to be determined. Moreover, the duration, sequence and objectives of the mobility phases (C.2) have to be specified. Additionally, a set of topics for the supporting e-learning lectures (C.3) must be selected, addressing professional and methodological as well as transversal competencies for the students.

In a second phase (D), the roles and expectations on both teachers (D.1) and supervisors (D.2) have to be detailed. This includes to define "who teaches what and when" as well as the learning outcomes and outputs for the students.

A third phase addresses the development of a concept for the quality assurance of the curriculum (E). In this context, an evaluation plan (E.1) and specific evaluation criteria (E.2) must be defined.

Lastly, the communication between the different stakeholders has to be set (F). For this purpose, the communication infrastructure and required tools are selected, e.g. for web-conferences. A first schedule for the communication between the different stakeholders is specified, especially taking into account the virtual cooperation and collaboration phases (F.1-F.3). *Table 2* shows a detailed use case for the course elements of the development phases C-F based on the European Engineering Team (EET).

Table 2. Use case for the course elements for the development phases C-F

C Educational contents
C.1 Project working phase: The project topic for the EET is to find a solution for breaking the chain of infection by developing an autonomous disinfection vehicle for application in hospitals based on the Sustainable Development Goals of the United Nations. This covers the development of a prototype as well as the development of a suitable business model. A sub-group of 4-8 students will be working on one topic supervised by four teachers from the partner universities.
C.2 Mobility phases: Four mobility phases at each of the partner universities are planned, one at each partner university with a duration of five days: week 14, Milan – introductions, define and analyze the problem to be solved; week 19, Trondheim – refine the problem definition and candidate solutions; week 41, Berlin – active prototyping; week 2, Warsaw – final meeting and introduction of the solution to investors.
C.3 E-learning lectures: For assisting the project work of the students the following e-learning lectures have been defined: Sustainable Value Creation, Systems Thinking & Systems Engineering, Technology Management, Circular Economy, Development of sustainability-oriented Startups, Sustainable Supply Chain Management, Virtual and Augmented Reality, and Digital Factory. The partner universities are recording the screen-casts and are prepare an exercise for each topic.
D. Roles of and expectations on teachers and learners
D.1 Roles of and expectations on teachers: For the EET, two different roles are required to be taken by the teachers: lecturer for the e-learning contents and supervisor for the project work of the students. The teachers are expected to be PhD students, post docs, or professors. Moreover, the teachers must attend all mobility phases and must closely supervise a small sub group of up to five students according to their individual competencies.
D.2 Roles of and expectations on learners: The students (learners) are expected to take different roles according to the project, such as project managers, product developers, or business model developers. In terms of the learning outcomes, the following expectations have been determined: ability to critically assess the goodness of a solution and its ability to meet a real customer's need; ability to work together and at the same time work in smaller groups that are capable of effectively sharing information between themselves; demonstrate (virtual) communications techniques learned during the project; ability to structure plans that address interdependencies and pre-requisites between the groups; ability to use abstract methods such as digital simulation or drawing to support decision making and design; ability to critically assess the contributions of a proposed solution to sustainable development. As output during the course, the students need to produce different reports including a reflection on the progress of the project work as well as a description of the produced results. Furthermore, the students have to create presentations for each mobility phase.
E Concept for quality assurance
E.1 Evaluation plan: It is necessary to monitor the learning and teaching progress and outcomes. During the course, three course evaluations are carried out with the participating students based on an anonymous online questionnaire. At the end of the EET an evaluation and improvement workshop is carried out by the teachers. As part of the workshop, feedback and possible improvement measures will be discussed with the students during their last mobility phase.
E.2 Evaluation criteria: For monitoring qualitative evaluation criteria, the change in the intercultural, mobility, methodical, professional, and self- competence of each student are evaluated during the anonymous online questionnaires. Therefore, the students rate their competencies in terms of speaking/understanding/writing English, sustainability, dealing with valued rules/norms, and expectations of people from other cultures, startup development, etc.
F Communication between the stakeholders
F.1 Communication of teachers and leaners: The infrastructure for communication between teachers and learners is designed as an open-source web-based platform. Moreover, the teachers and students meet physically at the mobility phases and virtually during the project work on the basis of web-based conference calls.
F.2 Communication between students for the virtual cooperation and collaboration phases: The communication between the students is organized in a decentralized manner. The students themselves chose within their group, the relevant digital tools for organizing their work.
F.3 Communication between teachers: The communication between the teachers takes place during the mobility phases, as well as by using web-based conference calls.

3.3 Implementation, Evaluation, and Follow-Up

This final section of the guideline includes recommendations for project management, for implementing the educational contents, and for continuous evaluation. The implementation of the course model entails an effective transnational project management (G) of the curriculum. This requires the adherence to responsibilities and scheduled meetings as well as the usage of the digital, communication tools. Secondly, the educational contents have to be implemented (H). This activity comprises the acquisition of students (H.1) as well as the operational planning and execution of the mobility phases (H.2), the virtual cooperation and collaboration phases (H.3), and the e-learning lectures (H.4). After the course is implemented and performed, evaluation and follow-up actions (I) ensure the educational quality of the curriculum and identify possible criticalities and subsequent improvements.

4 SUMMARY AND ACKNOWLEDGMENTS

The paper addressed the definition of a guideline for planning and implementing an action-based and transnational course in higher education for training the engineering competencies required in a future dynamic European workplace and economy. The main activities highlighted were: preparation, development of the course model, as well as implementation, evaluation, and follow-up. Important development phases for the main activities were explained on the basis of a real implementation of a master course focusing on the development of sustainable and technological innovations with entrepreneurial objectives.

This research was supported by the ERASMUS+ Strategic Partnerships Project “New Culture in Higher Education: Project-Oriented Learning Beyond Borders” funded by the European Union, project number 2015-1-DE01-KA203-002207.

Challenges for teaching sustainability and promoting diversity within a software engineering course

Graham Collins
Senior Teaching Fellow
University College London
United Kingdom
E-mail: g.collins@ucl.ac.uk

ABSTRACT

This report covers the challenges of integrating sustainability into the curricula of an undergraduate module for software engineering students and ensuring an inclusive and research based learning environment. Making skills audits explicit to team members provided a mechanism to help identify topics students wanted to learn and skills they needed for their projects. These audits particularly identified females' interests in sustainability and a chance to collaborate more widely, which helped identify a suitable research project and industry partner. Ensuring that there were no lone females in any project team necessitated larger groups, requiring more detailed attention to team structure and communications but provided greater opportunities for students to develop knowledge in areas that they wished. Documenting skills and discussing the different views of stakeholders: potential users of the software product, team members, industry teams and research groups across the university, also provided an appreciation of the value of diversity. Integrating projects that cover the topics female students have identified has provided a path for increasing sustainability education within the curricula and provided opportunities to pursue their interests. Experience suggests larger agile research teams may provide a route to supporting women in engineering and developing their potential in leadership.

Conference Key Areas: Sustainability and Engineering Education, Gender and Diversity, Attractiveness of Engineering Education

Keywords: sustainability, software engineering, women in engineering, diversity

INTRODUCTION

There has been a continuing problem for years of under-representation of females in STEM subjects [1]. This paper outlines the challenges in addressing this issue while also trying to ensure sustainability is integral to the curricula of a technology management module and aligned to the humanitarian objectives of the university and UN Sustainability Development Goals (SDGs) [2]. Identifying student's interests and aspirations helped develop a suitable undergraduate research project, as well as create an improved understanding of each team member's goals. Detailed skills audits (see section 2.1) clarified students' interests; brought to the fore female students' interests in wider topics within their subject, particularly regarding sustainability and opportunities to collaborate, and male students' interests in developing a complete solution. Working in larger teams not only gave individuals a greater opportunity to work on topics they wanted to learn, but also facilitated a supportive environment and an understanding that diversity enhances teamwork and research.

1 BACKGROUND

Improving diversity in engineering enhances creating solutions that inherently meet the needs of the wider population, not just solutions based on a narrow range of perspectives [3]. Improving diversity also aids innovation, the economic success of organisations, addresses the engineering skills shortage and contributes to creating a fairer society [3], [4]. University College London (UCL), Faculty of Engineering Sciences is dedicated to promoting diversity and increasing the number of women within engineering careers. The Department of Computer Science, within this faculty, has gained recognition for initiatives to support women in engineering in achieving an Athena Swan Silver award [5].

This paper covers the technology management module for final year undergraduate computer science students for the academic year 2015/16. This module is now integrated into other engineering courses. It covers the experience of ensuring research-based projects, problem-based learning (PBL) [6] and curricula are in line with the recommendations of professional bodies and leading engineering education reviews [7], [8] and content is co-evolved with students. To avoid gender bias and sole females in project teams, larger sized groups were required. This created the need for more detailed attention to boundary communications [9], how the teams were split along architectural lines and a focus on industry team structures and their approaches to acknowledging each team member's contribution.

There is recognition that organisations need to attract what Eric Schmidt, chief executive of Alphabet, and the holding organization of Google terms "learning animals"; employees who want to embrace life-long learning, willingness to continually learn new technologies and processes [10]. The wider social and teamwork skills are often just as important, if not more so [6] if we are going to develop the necessary collaborative skills needed in research and business.

Highlighting problems from other cities around the world helped engage students from the diverse cultures within the class and helped them appreciate that the research is aimed at solving a global problem. The project was placed in context of the UN sustainable development goals and the sustainable initiatives of the university, UCL Grand Challenges [11].

Students during the previous academic year had delivered research projects in the form of apps to enhance bicycle hire provision [12]. This theme of sustainable living continued for projects for the year 2015/16. Each team were encouraged to develop a solution of their own choice that would suggest routes or areas with lower levels of air pollution for those walking or cycling in London. Students were given the option to suggest an alternative project, to facilitate a more sustainable future and improve health and were encouraged to seek feedback from the intended users of their app as well as from an appropriate industry partner.

2 CHALLENGES

2.1 Integrating sustainability into the curriculum

Understanding of what students wanted to learn was gathered via feedback, retrospectives and project reviews. An in-depth understanding of goals and aspirations helped all team members and tutors understand what each individual wanted to achieve, what they could contribute and what they wanted to learn and helped everyone appreciate each other's skills. Subjects identified from female students' feedback included: sustainability, opportunities to collaborate and an emphasis on the wider aspects of computing. Feedback from male students included technical interests, relating to building data-intensive applications and behaviour driven development (BDD). Integrating the needs of Education for Sustainable Development (ESD) within a crowded curriculum was a challenge. Sustainability is a contested concept. However, there is general agreement according to Hasse [13], that it covers social, environmental and economic concerns. In addition, Haase considers that the different perspectives and models may help students develop the necessary critical pedagogic experience to understand different stakeholders' viewpoints.

2.2 Integrating the interests of female students

Studies of female students show a higher percentage participation in health and medical technologies, design, and biotechnology [14]. As feedback and skills audits from this module, indicated that female students were interested in pollution and health, it was agreed that students would be encouraged to develop apps to reduce exposure to air pollution. For this course feedback from female students also indicated that opportunities to work collaboratively in projects aligned to industry and sustainability were important issues. So it would seem logical to assume that courses with a focus on projects that overlap these interests may enhance the participation of female students.

2.3 Ensuring females are supported by their peers

In discussing STEM self-concept, Simpkins et al., [15] have considered how one's belief in one's abilities, based on the perception of others, can affect pedagogic outcomes. Rachael Robnett [16], outlines evidence that gender bias is antecedent to self-concept [17]. Robnett further highlights evidence that bias often originates from male peers, and this is further exacerbated in fields where females are severely underrepresented. To this end, to ensure a reduction in gender bias and that there were no lone females, an issue of concern highlighted by Beddoes [18], the class was split into 6 teams, of either 13 or 14 students, ensuring at least two females in each team. Eccles and Wigfield [19] suggest that ensuring that females are supported via their peers and teachers can improve their self-concept and that ensuring support by mentors would enhance this further. Female students were therefore encouraged to select someone they considered supportive from another team, to help with retrospectives.

Where research goals are clarified and females have their peers' affirmation, the development of effective team building skills necessary for engineering projects is enhanced [20]. Also, aligning the goals to the values of peers and society, the perceived value of the research is likely to be raised. As the problems associated with air pollution are a societal concern, all teams considered that opportunities to create an app to reduce exposure were an opportunity to create something worthwhile, learn new skills, and engage with research initiatives across the university covering sustainable cities.

The lecturers were invited to have access to team online project areas, in contrast to making this a course requirement in previous years. This seemed to create more openness over project issues as well as approaches to resolve problems. As *Table 1* shows, the percentage of communications initiated by females were higher than would be expected from the percentage representation within their teams. (Tools selected by students included: Trello, Slack, Jira, GoogleHangouts and Microsoft Visual Team Studio.)

Table 1. The data shown for two project teams, tracking just one of their software communication tools, Trello, within project weeks 2 to 6. Teams A and B both consisted of 3 female and 11 male students. (Letters have been substituted for actual project names for anonymity.)

Project Team	Number of communications tracked	Number of female initiated communications	% female within project team	% female initiated communications
A	112	60	21	54
B	102	56	21	55

As in previous years, females were encouraged and supported in taking on leadership roles for projects, as advocated within WISE publications [21]. Female students considered the structures and being allowed to elicit support from their peers during retrospectives helped them to contribute and develop their project management skills.

"Being the first practical insight I had into the Agile Methodology, this project enabled me to grow from a management, teamwork and leadership perspective. Throughout the development process, I seriously improved my self-discipline, which was crucial in order to properly manage my team to success." (Female student)

Challenge 2.4 Initial concern regarding team size

The opportunity to work in a larger team than students had previously experienced during their studies created an initial concern for one team. Students mentioned that they had not experienced these large groups before, and were concerned that they would only have a limited time to get to know one another. With students asking for advice how to split teams and plan communications, team structure examples were outlined; covering "Inverse Conway's Manoeuvre" [22] ensuring the team structure reflects and supports the architecture of the app, and also boundary communications with sub-teams and their industry collaborators.

3. DISCUSSION

To ensure student-centred learning "flipped lectures" were adopted, providing key research papers the week before discussing these in class and considering how findings could be applied to their projects.

The Adair model was introduced as outlined by Braun and colleagues [23], with an explanation that this is often used in industry as a framework for skills audits: what skills individuals need to develop, what skills the team require, what skills are necessary for the project. Students were encouraged to view this not as a static document but as a tool to help identify the necessary skills throughout the project, as well as self-appraisal, sub-team and project appraisal at the end of the project.

From audits, class questions and project reviews, it was apparent that all students were keen to link these to the UCL Grand Challenges. Male students were particularly keen to build working apps, as one commented: “from beginning to end”. Not surprisingly, as this was a computing module, virtually all skills audit comments, including those from female students, covered their wish to improve their software development skills and machine learning techniques.

“As a member of the research team, I also got the chance to work on something that I have long planned to learn, R programming. Working together with … we implemented 3 models for NO2, PM2.5 and PM10 … but also learn more things about linear regressions and hypothesis testing.” (Female student)

Working prototype apps, reports, and videos were delivered within 9 weeks. All project teams elicited feedback from: industry partners, potential users and the class, to improve designs and digital accessibility of their prototypes. Apps are being currently developed further by organisations, such as the London Sustainability Exchange (LSx) [24] a not for profit community-based organisation, set-up to enhance the sustainability of London. All teams expressed positive views that they had the opportunity to produce something tangible to improve sustainability and provide an opportunity for those living in cities to lower their exposure to air pollution.

Rogojanu and Badea outline that ESD encapsulates an attitude to the environment and ethical aspects [25]. One team negotiated a slightly different focus for their project, based on estimating the pollution level residents may be exposed to for properties available for rental or sale. They developed an air pollution app to be incorporated within the website of the online property sales and rental organisation they were collaborating with. During prototype discussions in class, the team outlined the dilemmas faced, with uncertainty whether properties associated with high levels of pollutants will actually have air quality data shown on the property website. These discussions were invaluable in helping students appreciate the ethics associated with sustainable engineering solutions and the perspectives of different stakeholders.

The course integrated the technology with coverage of technology management with an emphasis on communication and design decisions. Detailed investigations of the data sets and the different viewpoints of the designs from potential users, industry partners and other researchers at UCL also provided a range of improvements. One team utilised traffic noise open data, as an effective proxy measure for air pollutants. Recording design decisions and alternatives also supported the ethos of the course considering opinions from all stakeholders.

4. CONCLUSIONS AND FURTHER WORK

It has been shown by EU sponsored surveys [26] that females are more concerned with air pollution than males. Carefully selecting related engineering projects may, therefore, help promote engagement and increase numbers from female students. Kolmos et al., [14] have indicated that female engagement may be further encouraged by interaction with female professional engineers in the workplace. It was noticeable that students had specific interests during this project, covering technical areas, sustainability or ethics. Female students showed a particular interest in sustainability topics, which were integrated throughout the course. Male students showed specific interests in application development, such as the node.js platform, and coding approaches that could be understood by both technical and business users. The nexus of interests, from both genders, aided collaboration with industry partners and ensured engagement with this research from all teams. This also provides further opportunities to track students' engagement, whatever their initial interests, and ensures that their progression and development of skills for each category of interest are met. This is particularly important if we are to further improve diversity and inclusion initiatives.

We need to consider how students learn in a more holistic way and consider students' methods of learning, including cognitive and affective [27]. The project structures allowed teams to work in an environment of psychological safety and the opportunity to ask for support during retrospectives increased openness and encouraged a higher level of participation, especially from female students. An inclusive environment was further fostered, by encouraging students to support their peers and join specific support groups at UCL [28].

Research papers often point to small team size covering agile software practices [29]. However, further understanding of optimal team size for education is an area of research that needs investigation, especially as there is a trend in technology organisations to adopt larger team sizes [30]. This also created a need for more detailed peer assessments to show the contributions of individuals and what the project would have been like without their support. The larger size of the project teams, compared to other courses in the department, allowed for specialism and ensured there were no "token" females in each group.

"By working on the project with the big team, it makes me realize how we can manage the project and team relationship effectively using sprint iterations." (Female student)

"Comparing with my previous teamwork and team lead experiences, I noticed a fair improvement of my time management and planning skills. This was mostly due to the fact that I learnt to rely on others, instead of taking care of every issue myself. Although I am a perfectionist through nature, the complexity of this project forced me to pass over responsibilities to the Point Persons [responsible for the task]." (Female student)

Teams were encouraged to develop detailed skills audits, which created the opportunity to identify the knowledge and skills individuals wanted to learn and share, and recognition that everyone has something valuable to contribute. Many students considered they had developed a better understanding of complex sustainability issues from consideration of the different viewpoints from potential users of their app, industry partners and other research groups within the university. Discussions regarding the interpretation of pollution and health data, software architecture decisions and approaches to software development and communications also helped them gain a better appreciation of the value of diversity, and that everyone brings valuable experiences and skills to a team.

"We all have different backgrounds, different personalities, different habits and different ways of working. I learnt to enjoy the differences in our cultures and respect one another." (Female student)

5. ACKNOWLEDGEMENTS

I'm grateful for the support from my colleagues in teaching this module, Hugh Varilly, Royal Academy of Engineering Visiting Professor and teaching assistant Maria Murcia Lopez.

ABSTRACT

The role of engineering education is essential in global sustainability transformation, considering the impact technology has on the environment and societies. Many suggestions have been made on what competences universities should teach to educate game changers and how to improve sustainability literacy. Despite the growing number of studies in the field, research is scarce on how to assess what the students know about global sustainability challenges and how to embed sustainability literacy into curricula. This paper presents the first experiences on using a sustainability literacy test (the Sulitest) as a teaching tool. The test was developed in 2012, and it includes global and national questions on multifaceted sustainability challenges. Our results are based on national questions created for the Nordic countries and on the test results we got from 700 students in Finland, Sweden and Norway. The Sulitest seems to be useful as a teaching tool, but the national questions ought to be re-evaluated to achieve balance between different aspects of sustainability. The test has weaknesses regarding its use as a curricula development tool, but it can facilitate teachers in engineering education in drawing a comprehensive picture on the problems the future engineers are required to solve.

Conference Key Areas: Sustainability and Engineering Education, Curriculum Development, Engineering Skills
Keywords: Sustainability Learning, Literacy Test, Nordic universities

INTRODUCTION

Engineering education needs to adapt to the global sustainability transformation, which has been widely acknowledged [1]. Engineering associations in the west point to competences for solving 21th century challenges, and a number of scholars find engineering curricula in the midst of a paradigm change from “how to integrate sustainability into our discipline” to “how our discipline can contribute to sustainability” [2, 3]. Such scholars emphasise that engineers need holistic understanding on the environmental, societal and economic impacts of their profession, and advocate for generic and interdisciplinary skills. Moreover, engineering education should focus also on the values, behaviour and problem solving skills in order to solve wicked problems, in addition to the technical expertise and specific knowledge they acquire from their studies.

Many teachers worldwide have made efforts to tackle the challenge of combining sustainability transformation and engineering education. Contributions vary from individual methods, including online learning [4], games [5] and concept maps [6] to wider measures such as a dedicated program for sustainability engineering combining different engineering fields [7], multiple course-specific sustainability components integrated in chemical engineering curricula courses [8] and integrating sustainability into learning outcomes of courses or programs [9]. By way of illustration Segalas et al. [9] study three European technical universities' bachelor programs, and find none of the sustainability competences under investigation contained a learning outcome "world current situation", despite of the otherwise sustainability-oriented learning outcomes.

In fact, in the global research concerning sustainability in higher education, the question of key sustainability competences has raised debate over what and how, we should teach in order to empower the students to contribute to sustainability transition [see for example 10, 11]. Some of the most commonly agreed competences are systems thinking, integrative and holistic thinking, strategic and collaborative competences [12], whereas some of the most used teaching methods across disciplines include problem-based learning, case studies, group discussions and critical writing tasks [13].

However, knowledge on current global sustainability challenges, "the world current situation", is a fundamental precondition for learning on how to promote sustainability transition**.** According to UNESCO [14], education for sustainable development (ESD) should include several issues, including climate change, biodiversity, poverty and disaster reduction, sustainable consumptions and market adaptation. Moreover, engineering innovates solutions to sustainability challenges in one scale, but may produce sustainability challenges in another. Therefore, there is a need to define what should be included in this "basic knowledge set" of world's current situation.

One opening was made in 2012 in the form of an international, internet-based test containing different global challenges, and covering all the pillars of sustainability. This Sustainability Literacy Test (Sulitest) was created as the response to the goals set in the United Nation's (UN) Rio+20 world sustainability summit, and it's also closely aligned to the 17 Sustainable Development Goals of the UN Agenda 2030 for Sustainable Development. Sulitest development was guided by over 300 contributors and its panel of senior and regional advisors, including the UN, the UN Development Program (UNDP), the Globally Responsible Leadership Initiative (GRLI), the UN Educational, Scientific and Cultural Organization (UNESCO) and the International Association of Universities.

The test aims to facilitate higher education teachers to assess their students' knowledge and skills on sustainability and works as a means for testing participants' sustainability awareness. The Sulitest has already been adopted to hundreds of universities all over the world, and over 40000 students have taken the test by the end of 2016. However, scientific discussion is yet to be opened on its benefits and disadvantages as a teaching and assessment tool in higher education. In fact, research in general is very scarce concerning the use of tests as teaching or assessing tools in sustainability education.

This paper discusses the first experiences gained from the Sulitest in a Nordic project, which aimed to find new ways to evaluate student's sustainability literacy across disciplines. The paper examines features of the Sulitest and Nordic university students' sustainability literacy, and discusses the test as a tool for integrating sustainability into engineering education. Finally, the paper reflects on how making engineering and interdisciplinary study can contribute to sustainability, to paraphrase Mulder [3]. The results will benefit teachers in higher education interested in promoting sustainability literacy, regardless of discipline, to familiarize themselves with different aspects of the Sulitest.

1 NORDIC SULITEST PROJECT

1.1. Sustainability in Nordic higher education

The Nordic countries are renowned for their ambitious strategies for sustainable development, and they target at leading the way in ESD [15, 16]. For example, at the Norwegian University of Science and Technology (NTNU), interdisciplinary environmental oriented courses with different approaches and perspectives have been mandatory for the engineering students for more than 25 years and according to a recent overview from the NTNU Sustainability Programme, more than a 100 courses are connected to sustainability concepts [17]. However, recent research has on the other hand suggested that Nordic universities follow a global trend [18, 19] in emphasizing campus operations over sustainability education [20], and that sustainability is inefficiently integrated in the learning outcomes of Nordic universities' courses and programs [21]. Moreover, Boman and Andersson [22] found that only 1/3 of the courses in the University of Gothenburg, Sweden, include sustainability contents.

The factors affecting sustainability integration in higher education are multifaceted. In the research done in the Nordic countries, mainly focused on Swedish case examples, the role of good leadership, clear strategy, environmental management systems and collaboration have been highlighted to promote institutional sustainability [23-26]. However, major global challenges for teachers to integrate sustainability in their teaching seem to be overcrowded curricula, lack of resources or insufficient competences in sustainability [27-29]. Therefore, evaluation tools, such as the Sulitest, with which teachers could get an understanding of the students' sustainability competences, while students acquire sustainability knowledge and obtain generic competences, would be useful.

1.2. Description of the project

The Sulitest is designed to include a global set of questions (module) and a regional/local module. All researchers and teachers are free to suggest questions for the global question pool, after which they are validated by a Sulitest board and added to the test platform. However, in the case of the local questions, it is up to each country or region if the questions will be created or not. The Nordic universities took the challenge in 2015-2016 and created national modules for Finland, Sweden, Norway, Denmark and the Faroe Islands, utilizing the experiences acquired from the first pilot test in Finland during 2014-2015. Also additional 5 questions on Nordic-level sustainability challenges were included in each national module. The final number of questions in the new modules varied between 25 and 31, depending on the country.

The project included also the piloting of the new questions with each partnering universities' students. Four Nordic universities from Norway, Sweden and Finland piloted the Sulitest with their national modules during spring 2017. This paper is based on the results from those pilots. The piloting institutions chose themselves the matrix design of using the Sulitest: as an assessment tool for exploring sustainability literacy, as a teaching tool offering the students the opportunity to study the Sulitest questions with the references they include, or as a tool to introduce the students to the subject. Moreover, all the institutions were instructed to ask the students to fill in an optional background survey following the 50 Sulitest questions, which includes questions on age, gender, discipline and interest toward sustainability.

1.3 Description of the Sulitest architecture

One important feature of the test is the architecture of the questions: the questions should be designed so that there are equal amount of questions belonging to each Sulitest-theme. Preferably, the distribution should be even also in the 24 subjects classified under the 7 themes (see Table 1 for the themes and subjects). Moreover, to facilitate research purposes, the questions must be tagged with at least one sub-subject out of 42, which tells even more precisely what sustainability challenge is discussed in that question.

Table 1. The architecture of the Sulitest: themes and subjects.

Themes	**Subjects**
1. Sustainable humanity and ecosystems on planet Earth	1. Ecosystems: Biosphere, global and local ecosystems, interdependent and diverse community of life, life supporting cycles, system closed (materials) / open (energy), etc. 2. Humanity: Individual human needs, diversity, social fabric, cultures, local and global world, etc 3. Sustainability: Definition of Sustainability / Sustainable development 4. Ecological perspective : where are we at, and why sustainability is both an urgency and an opportunity 5. Social perspective : where are we at (demography, (in)equalities, gender equality, education, …), and sustainability being an urgency and an opportunity
2. Global and local human-constructed systems to answer people's needs	6. Local and global social structures and governance: paradigms; positive results negative impacts; laws; how organisations work; land use; gender equality; etc. 7. Within local and global social structures and governance, zooms on : Education, and Culture 8. Local and global economic systems: paradigms; positive results negative impacts; production, distribution, consumption of goods and services; life cycles; value chains; finances; etc. 9. Within local and global economic system, zooms on : Water, Energy, and Food
3. Transitions towards sustainability	10. How to start, reinforce, accelerate systems change 11. Initiatives towards sustainability … more from institution / int'l level (like UN MDGs, Global Compact, GIEC, GRI, ISO 26000, ESD, etc.) 12. Concepts, tools, frameworks … more from individual NGOs or smaller networks (like Cradle to Cradle, Natural Capitalism, The Natural Step, Ecological Footprint, etc.) 13. Examples and ideas we can learn from: case studies of successes or failures ; technological, strategic, or social innovations
4. We each have roles to play to create and maintain individual and systemic changes	14. How does one become aware of his own roles and impacts … whoever "one "is (individual, organisation, south, north, etc.) 15. How does one efficiently act to create both individual and system change … whoever "one "is (individual, organisation, south, north, etc.)
5. Personal Skills	16. Ability to reflect/self-evaluate alone and in a group; Ability to constantly renew energy; Ability to continuously to learn/develop; Creativity; Critical thinking 17. Capacity for empathy, compassion, solidarity; Futures-oriented and strategic thinking 18. Dealing with complexity and uncertainty; Practical problem-solving / management / planning skills
6. Working with others	19. Networking; Communication skills; building effective coalitions for systemic change 20. Catalysing / managing change; Inspire a shared vision; Enable/Motivating others to act/participate 21. Teamwork; Work in multi-cultural and interdisciplinary (diverse) settings; Participatory skills, decision-making; Conflict resolution skills/consensus building; Focus on process, dialogue, listening;
7.Think and act systemically	22. Ability to put in practice systems thinking concepts; identify and use leverage points 23. Ability to zoom in and out in time and details, and to keep the desired future and global perspective in mind 24. Ability to understand formal and informal structures, power dynamics, and interactions

This paper presents the first results of sustainability literacy levels of Nordic higher education students, and preliminary descriptions on the factors affecting the test results. Moreover, the aim is to initiate discussion on the Sulitest as a tool for sustainability education. For the tool is rather new, it's essential to explore the quality of the created national questions, and what causes may lie behind the questions revealing to be among the easiest or the most demanding ones.

The detailed research questions are:

1. What are the average scores of Finnish, Swedish and Norwegian students?
2. Which factors affect the scores of the Nordic students?
3. How equally the national questions are distributed to the different Sulitest themes?
4. Do the different modules of the Sulitest include questions that are on average very easy or very demanding (over 70% respond correctly / incorrectly)?
5. If there are clear differences in the degree of difficulty of certain questions, are there any common factors in the questions that may explain the trend?

2 RESEARCH FRAMEWORK AND METHODS

The motivation for this study was to explore the usability of the Sustainability Literacy Test (Sulitest) as a teaching and curricula-development tool. We succeeded in having test results from 3 technical and 2 other universities in Norway, Sweden and Finland, the amount of responses being finally 700 in total. The students represented multiple fields, including business, law, water and environmental engineering, sustainability, environmental sciences, environmental management and corporate governance.

The main purpose of the Nordic project's pilots was to gain experiences on how the test could be used in teaching, and to explore if there were too trivial or too demanding questions. Moreover, the project signalled the importance of sustainability issues to students, and that the topic is of great concern to higher education institutions. The most demanding and easiest questions were defined to be those, which <70% or >70% answered correctly, respectively, and were analysed with qualitative content analyses to find out the possible factors explaining the difficulty/easiness. The content analyses was conducted using open coding, based on which classifications for easy and difficult questions were created. The factors affecting the students' sustainability literacy were analysed quantitatively.

As the data was not collected with an empirical research setting, the backgrounds and amounts of students varied substantially between the piloting institutions. Therefore, the approach of this study is explorative, and the results on the students' literacy only suggestive. Moreover, the limited amount of background survey data allowed quantitative analyses for only some of the surveyed factors (only 220 students answered the survey).

3 RESULTS

3.1 Which factors affect Sulitest scores?

The total scores of the students from Finland and Norway were a bit above international reference scores (51% for international module). In all the countries, the international module seemed to be easier for the students compared to the national module. The total results for Sweden were significantly lower compared with both Finland ($p<0,001$, $F=19,193$, one-way Anova) and Norway ($p<0,21$, $F=19,193$). All the average scores are presented in Table 2.

Table 2. The averages of the Sulitest scores from Finland, Sweden and Norway. In counting the national module scores, the results from the students who indicated in the Sulitest background survey being of other nationality than Finnish, Swedish or Norwegian, were excluded.

Sulitest Module (n of questions responded)	Countries							
	Finland		Sweden		Norway		All countries	
	N respon-dents	% correct	N respon-dents	% correct	N respon-dents	% correct	N respon-dents	% correct
International (30)	199	57%	453	50%	48	60%	700	53%
National (20)	157	50%	440	44%	40	46%	637	47%
All questions (50)	199	53%	453	45%	48	52%	700	48%

The vast majority of all the respondents represented Master's degree students, except for Sweden, where 44% of the 106 students who responded the background survey, were bachelor students. However, there was no statistically significant differences between the scores of bachelor and master students, but instead, age seemed to have a positive correlation with the total test score (Fig. 1, r=0,22, p<0,001). Gender instead had no effect on the total scores.

The students responding the Sulitest represented mostly business, law and engineering fields, with only a few students representing other fields, such as arts, humanities and communications. However, since 82% of the 220 students who indicated their discipline in the background survey, represented business and law, the effect of discipline on the scores was not explored.

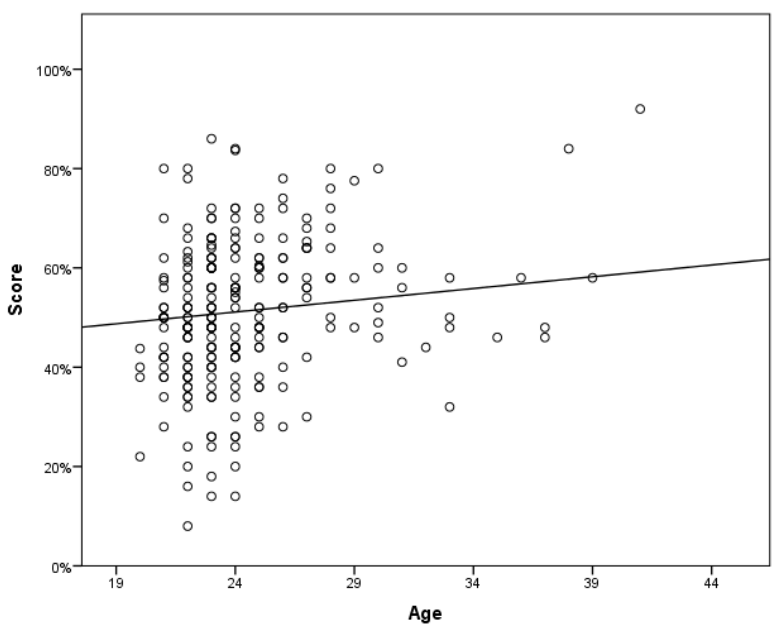

Figure 1. There was a positive correlation between age and total scores of the Sulitest (r=0,22, p<0,001), N = 256.

The nationality of the students seemed to have a minor, yet not significant, effect on the scores: the Nordic nationalities scored better in the national modules compared to the nationalities coming from outside of Nordic countries (international students), whereas the international students scored on average slightly better in the international module (Table 3). Moreover, minor difference was observed between different Nordic nationalities in answering two joint Nordic questions: The Finnish respondents scored better (49%) in a question concerning the eutrophication of the Baltic Sea compared to the Swedish (29%) and Norwegian (25%), whereas the Swedish had better level of knowledge (88%) on the Nordic ecolabel Swan's contents than the Finnish students (40%) (the Norwegians did not answer the Swan-question).

Table 3. The average results of international students compared to Nordic nationalities. The results include only the students who responded the background survey.

Sulitest module	Nordic students		International	
	N	% correct	N	% correct
International	200	55%	58	59%
Finnish	68	50%	37	44%
Swedish	113	45%	13	43%
Norwegian	19	53%	8	36%
All questions	200	50%	58	52%

However, when exploring the effects of sustainability involvement or interest, which were asked in the background survey, there was a statistically significant difference between those who indicated they keep up with the news about sustainability often (n=74, score=57%) compared to those keeping up about the news only rarely (n=128, score=48%), (F=19,863, p<0,001, one-way Anova).

3.2 Quality of the questions

The quality of the national questions varied. The Norwegian module included several questions that revealed to be very challenging, as well as the Swedish module, while the Finnish questions all seemed to be moderate in their level of difficulty (Fig. 3). In all the national modules, theme number 4 was underrepresented compared to the number of questions in other themes, and in Finnish and Swedish modules themes 1 and 2 were somewhat overrepresented (Table 4).

Table 4. The distribution of questions used in the pilots according to Sulitest themes.

Theme	Module				
	International	Finnish	Swedish	Norwegian	All
1. Sustainable humanity and ecosystems on planet Earth	9	4	9	8	30
2. Global and local human-constructed systems to answer people's needs	10	11	11	5	37
3. Transitions towards sustainability	9	8	8	6	31
4. We each have roles to play to create and maintain individual and systemic changes	2	2	2	2	8
5. Personal Skills			1	3	3
6. Working with others				3	3
7.Think and act systemically				3	4
All themes	**30**	**25**	**31**	**30**	**116**

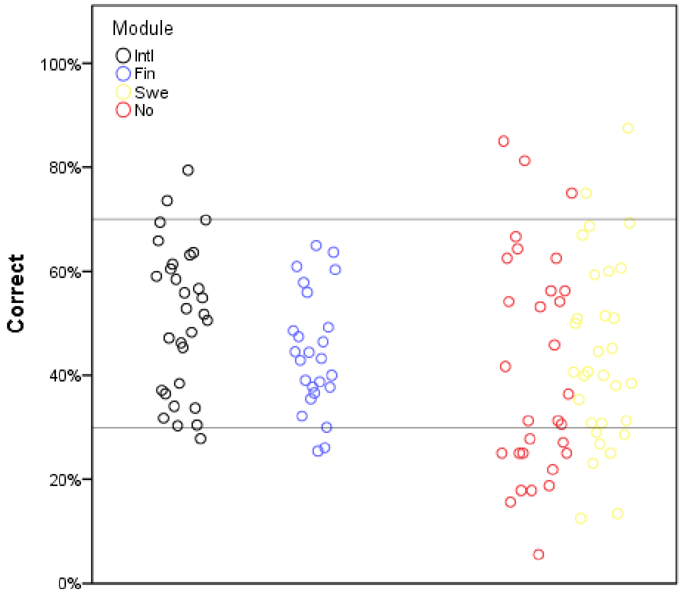

Figure 3. The difference in questions' difficulty in each module: In the Norwegian module, there are more difficult questions compared to the other modules.

Of all the 116 questions used in the pilot sessions, 25 revealed to be on average relatively difficult (<30% of respondents correct), and 9 relatively easy (>70% respondents correct). No explicit factors were found to explain why those particular questions were easy or difficult: they represented multiple subjects and themes. However, questions including statistics seemed to be challenging, specifically when the answering options were close to each other. The most difficult questions also required in many cases detailed knowledge on certain field, and the answering options were well designed making it hard to guess the expected answer. On the contrary, some of the easiest questions were designed in a way, which revealed the correct answer in the formulation of the question. In a few cases the correct answers were also quite evident, as the incorrect answering options were somewhat irrelevant considering the question formulation. (Table 5.).

Table 5. Factors affecting the difficulty of questions.

	Specific information on a field or actors	Statistics	Terminology	Correct answer can be guessed	General knowledge
Difficult questions	18	5	2		
Easy questions	1		1	4	3

4 DISCUSSION AND CONCLUSIONS

Having examined a cohort of 700 responses from students in Norway, Finland and Sweden, this section discusses the main findings. The results are examined against Mulder [3] on how engineering education may contribute to sustainability and how the results indicate interdisciplinary challenges.

Students indicating they follow the media on sustainability subjects seemed to score relatively high in the Sulitest. In addition, the easiest questions in the pilots revealed to include several subjects that are widely discussed in the Nordic public media, such as the effects of Chernobyl radiation, high global costs of climate change or the amount of electric cars in Norway. These results, added with the positive correlation of age and scores, suggest that sustainability literacy discussed in the Sulitest questions measures respondents' level of awareness, all-round education and personal interest, rather than the level a university has been teaching sustainability subjects. Thus, the Sulitest can be recommended only with caution as a tool to assess sustainability contents of curricula.

In addition, the questions used in the test vary from session to session due to the design of the Sulitest online platform: the system randomly selects a set of questions from a larger pool to a single test session. However, we found also the quality of the questions, as well as the representativeness of different Sulitest themes, varying substantially. The uneven distribution of questions concerning different themes may result in biases in students' scores: students having more experience from their studies concerning themes 1-2 might score higher than their peers studying a field that has emphasis on themes 3 or 4 (see Table 1 for the themes). This might make comparisons between different institutions or disciplines unreliable. We therefore suggest the national modules to be developed to a more balanced direction. Moreover, our findings suggest that the strength the Sulitest resides in its ability to evaluate progress from course to course, or within a course, rather than in comparing the scores between students, institutions or countries.

Thus, due to the imbalance of questions representing different themes, we recommend the test to be used by teachers as an introduction to sustainability, or as a teaching tool making good use of the references each question of the Sulitest includes. Segalas et al. [9], for example, called for a common definition on sustainability competences for engineering curricula to facilitate sustainability integration. Sulitest could, if properly developed, offer a framework for teaching world's current situation, reasons behind unsustainability, technological development and ability to act and solve problems. However, one needs to acknowledge that knowledge is not the only factor affecting the environmental performance of a person, but several factors contribute to it, such as country and culture, informal education, and personal motivation and attitudes [30]. To which degree students actually acquire sustainability knowledge and obtain generic competences in higher education was beyond the scope of this study, and invitations to study engineering pedagogy and the use of tests is most welcome.

For future development, we suggest re-evaluation of all the national modules to have appropriate and equal quality and balance between the themes. In addition, we recommend detailed analyses to be made on the students' test results before drawing conclusions on their literacy or making decisions on the curricula according to the test results. Moreover, an empirical study would be needed to investigate more thoroughly the factors having an effect on students' sustainability literacy, such as nationality, age or discipline. The fact that different Nordic nationalities gained varying results from a few questions on Nordic-level sustainability, is also interesting and raises a question if sustainability challenges or actions often considered Nordic, are after all more relevant to specific countries than to the whole region, and the subject could offer possibilities for future research with the Sulitest. Finally, it would be interesting to investigate teachers' motivation to use the test, for it contains many aspects beneficial for higher education.

To conclude, we consider the potential of the Sulitest substantial in teaching global sustainability challenges in universities. According to a short questionnaire by one piloting institution, the test revealed to be eye-opening for many students, presenting the considerable diversity of different fields, challenges, solutions, definitions, management practices and agreements relating to sustainability, added with references to the question sources. Therefore, despite its weaknesses as an assessment or curricula development tool, it can facilitate the teachers also in engineering education substantially in drawing a comprehensive picture on the problems the future engineers are required to solve, and on the interdisciplinary and interconnected nature of future working life.

ACKNOWLEDGEMENTS

We want to express our warmest gratitude to all partners in the Nordic project, and all the experts involved in creating the national modules. We additionally want to thank the Sulitest organization for the smooth collaboration and assistance in creating the national modules. This study wouldn't have been possible without the kind permission from the piloting universities to use the students' Sulitest results for analyses. The Nordic Sulitest project was funded by the Nordic Council of Ministers.

ABSTRACT

The paper presents the design-process of new bachelor/master-curricula at the Technische Universität Berlin. Examples for the successful integration of sustainability and entrepreneurship in the curricula are presented. The master program “innovation management, entrepreneurship and sustainability” and the one year orientation study program “MINTgrün” were introduced in detail. With the instruments of our quality-management-system the behaviour as well as the competencies of our graduates has been assessed. The centre of entrepreneurship gives support for the start-up foundation and helps in the cultural change on the way to an entrepreneurial university.

Conference Key Areas: Curriculum Development, Attractiveness of Engineering Education, Sustainabilty and Engineering Education

Keywords: Entrepreneurship, Sustainability, Curriculum Design, Quality Management

INTRODUCTION

The Technische Universität Berlin (TUB) offers 51 bachelor (Ba) and 73 master (Ma) study programs. 65 % of the fields of study of TUB are in engineering, 15 % in mathematics and natural sciences and 20 % in social sciences and humanities. Sustainability and Entrepreneurship are addressed in the mission statement of TUB. Both topics should be integrated in research and education as well. In the following we will show, how sustainability and entrepreneurship are integrated in our curricula. With the instruments of our quality-management-system (QMS) we have assessed, if students and graduates have been educated in the line of our mission statement.

1 DESIGN OF A NEW CURRICULUM

1.1 General design

The flexibility in the design of the curricula has been made possible by the Bologna-process. This process has led to the transformation of the one-cycle diploma curricula through the two-cycle Ba/Ma-system. The Bologna transformation of the curricula started at TUB in the year 2004/2005. Of specific significance was the paradigm change in the design-process, the so called shift from teaching to learning. Here, the workload as well as the competencies achieved by the students during the learning process has been taken into account in the design-process for a new Ba/Ma-curriculum. In the following, we describe the design-process and the structure of a Ba/Ma-curriculum at the TUB.

Altogether, the length of study of a consecutive Ba-/Ma-program does not exceed 5 years due to German law regulations. Thus, usually mainly three-year bachelor and two-year master are realized at TUB. Each year of study is organized in two semesters. A student should get 30 credit points in one semester according to the European Credit Transfer and Accumulation System (ECTS). The credit points are corresponding to the workload of the students. One credit point is equivalent to 30 hours of work. The resulting annual workload is 1,800 hours. If the students have finished the master they have achieved 300 credit points in the consecutive bachelor-master program. *Fig. 1* shows the schematic structure of a consecutive Ba/Ma-curriculum in engineering.

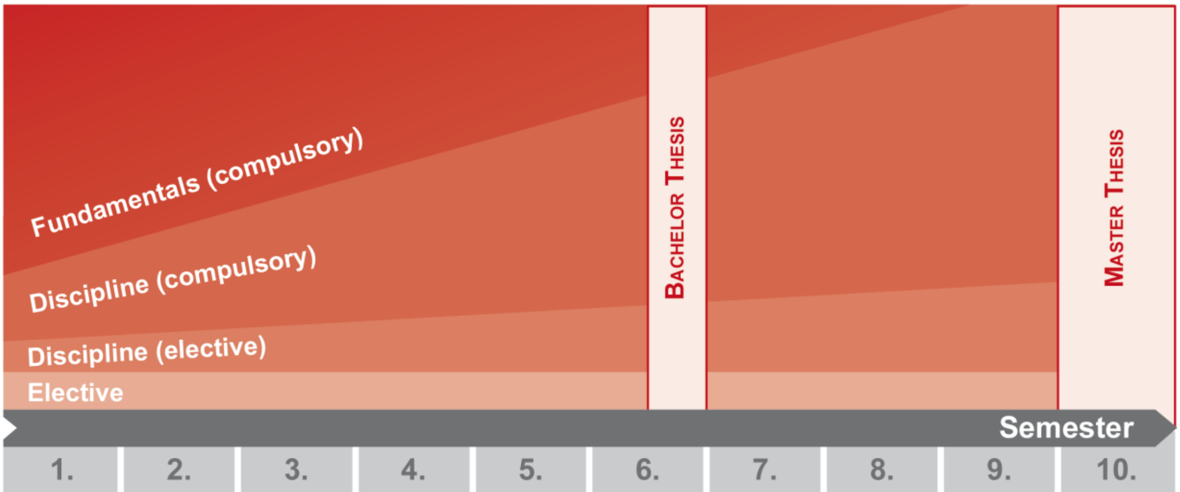

Fig. 1. Schematic Ba/Ma- curriculum in engineering at TUB.

The fundamentals (like mathematics, physics, mechanics and thermodynamics) dominate in the first semesters of the bachelor in engineering. Usually, they are compulsory. The new developed curricula of the bachelor programs include project work in the first semester courses on subjects of particular significance in the specific engineering discipline to increase the academic success. The curricula are constructed with modules. The workload of the modules is usually 6, 9 or 12 credit points. The compulsory part of the specific engineering discipline increases during the bachelor-semesters. An individual profiling of the students competencies is possible with the elective-compulsory part of the discipline and the free elective part of the curriculum. Both bachelor and master programs usually contain internships in industry (range between 6 and 12 credit points). They are part of the compulsory part of the specific engineering discipline. In the master programs the fundamental part is much smaller compared to the bachelor. The curriculum is dominated by the specific compulsory and the compulsory elective part. In the last semester the master thesis is elaborated. The formal design process of a curriculum is fixed in our QMS. However, the relevant content as well as the final curriculum is established in the faculty.

1.2 Entrepreneurial modules

Around 50% of the curricula of all Master degree programs require entrepreneurship courses as mandatory or semi-mandatory, for all other students these courses are elective. The courses are organized from offering basic knowledge and first contacts to entrepreneurs up to the development of business plans and proto-types. In detail, three of these modules are described in the following:

<u>Module venture campus (12 credit points):</u> The strategic aim of this course is sustainable support and economic exploitation of high- tech foundation potential of the students of the TUB. As a practically oriented course, venture campus is providing its students with all business and management skills required for the establishment of a start-up company. Within this course its participants are working closely together in interdisciplinary teams preparing business plans. Although the economic realization of the business plans of the participating teams is not required in reality it is highly acknowledged and around 30 start-ups were established out of this course in the last 10 years.

<u>Module entrepreneurship research (6 credit points):</u> In contrast to venture campus the entrepreneurship research course is theoretically oriented as it aims at giving students a state-of-the-art overview of all streams of research around the theme entrepreneurship. The course intends to shed light on different aspects from managing and aligning internal and external networks, all facets around founding enterprises, how to explore and develop markets, how to get and exploit creative ideas, the debate effectuation und causation, just to mention a few. The course studies both theoretical models and their empirical application, changing between micro and macro-economic perspectives with a strong methodological focus. This course may also be combined with venture campus resulting in a total of 18 credit points.

<u>Module innovation management and entrepreneurship (6 credit points):</u> This module is an integrative course on the basics of entrepreneurship and innovation management. The course focuses on the in-depth understanding of aspects as idea generation, technology-based entrepreneurship, marketing and markets, organization and project management, new product and process development, entrepreneurial finance and human resource development. The basic course is based on introductory lectures into the above mentioned topics. In addition, the students get lectures/presentations from entrepreneurs and visit entrepreneurial venues, companies, incubators, customers etc. In order to increase the practical relevance of the course lectures are complemented with team-work on case studies or small

entrepreneurial projects. The course is the basic course on entrepreneurship and innovation for students of European Institute of Innovation and Technology (EIT) master programs and is as all other courses above taught in English.

1.3 Sustainability modules

The number of modules with sustainability contents is significantly higher than those of the entrepreneurial modules. At least 30 modules with sustainability contents are identified so far. It is the plan for this year, to realize a sustainability certificate. This certificate will be given to Ba/Ma-students, which receive at least 18 credit points from modules with sustainability content.

“tu project” supports undergraduate students with a two-years funding for an own research project. These projects have been invented in the year 2012 and they are founded by the Federal Ministry of Education and Research [1]. According to the mission statement of the TUB the funded project should have a focus on sustainability and interdisciplinary teamwork. In order to start a tu project, two students have to write a project plan for a research topic. The project should run for two years and usually 15-20 students as participants should be involved. Usually, the student team is mixed in age and disciplines. According the specific workload, the participants receive credit points directly corresponding to their personal workload within the project. Up to now 34 tu projects have been realized. Topics range from “simulation game for technical environment protection” to “welfare accounting” and promise to yield new insights for the involved disciplines.

In the module “prototyping eco-innovation” aspects of sustainability and entrepreneurship have been combined.

2 EXAMPLES FOR NEW CURRICULA

2.1 Master innovation management, entrepreneurship and sustainability

Moreover, one master degree program (MSc) is specifically devoted to innovation management and entrepreneurship and is the most attractive one in Germany with more than 500 applicants for 35 places. It is the dual degree master`s program “innovation management and entrepreneurship” (IME) organized in cooperation with the University of Twente, the Warsaw School of Economics, the Higher School of Economics in Moscow, the St. Petersburg Polytechnical University and the Norwegian University of Science and Technology. Students are supposed to stay two semesters in Berlin and two semesters in one of the partner institutions. The compulsory area comprises 30 credit points. Modules are “entrepreneurship research”, “venture campus”, “innovation economics” and “strategic management”. In the compulsory elective part the students should select modules with a total of 30 credit points. 30 credit points are elective. It is strongly recommended, to elect courses in the fields of management, innovation management, entrepreneurship, business administration, economics and industrial engineering and management. The master`s thesis is usually completed in the fourth semester. It comprises 30 credit points. The last ranking 2015 based on the evaluation of human resource departments made by “Wirtschaftswoche” sees the entrepreneurship education at TUB among the top ranked business education in Germany. The eduniveral ranking 2015/16 ranked this master as the best in Germany and the number 42 worldwide. In the CHE Master Ranking 2014, the IME master is classified as Germany`s leading master program in 5 out of 14 categories. The IME is leading in “Study comfort”, “Practice focus”, Scientific focus”, “Support in international exchange” and in International orientation”. Recently, the curriculum was redesigned and a new sustainability track has been opened. In the winterterm 2017/2018 the new master “innovation management, entrepreneurship and sustainability” will start. The structure of entrepreneurship courses at TUB also served as blue-print for the educational programs at the EIT and was copied in many European universities.

2.2 Orientation study program MINTgrün

MINTgrün (English STEMgreen) is a one year orientation study program. It addresses high school graduates who are interested in natural sciences and engineering but don’t yet know what exactly to study. The superscript “grün” indicates the conceptual focus on ecological und social questions. The target of MINTgrün is to show them the several possibilities of a future in natural sciences, technology, engineering and mathematics. A special target group are young women, who miss aspects of sustainability in the regular engineering curricula. Mandatory courses are the “science window” and the “orientation course” as well as the “MINTgrün laboratories” (all 6 credit points). In the laboratories, real project work has to be done. Examples of the labs already have been published [2, 3]. In the mandatory elective part (42 credit points), the students can choose all modules within the university. Popular are modules like mathematics, physics and computer science (6 credit points). All received credit points are usually accepted if the students will change to another bachelor-degree program. MINTgrün started in 2012 with 77 students. The number of participants increases continuously up to 490 in the year 2016. Today, we have 38 % female students (average at TUB in engineering is 28 %, overall 33 %). The program enables approximately 82 % of the MINTgrün students to make an informed decision on their later field of study, 74 % of them stay in the field of STEM. 10 % see their future outside academic contexts. In the next 4 years we will investigate, if the success rate of former MINTgrün students is higher from those students, who choose their bachelor directly.

2.3 Master programs at the TUB- EUREF campus

At the TUB-European Energy Forum (EUREF) campus, three international MBA-degree-programs where actually offered since the year 2016: “energy management”, “european and international energy law” and “building sustainability – management methods for energy efficiency”. The new program “sustainability mobility management” will start in the winterterm 17/18. The energy transition of the society is in the focus in these master degree programs. The study location is on the site of the EUREF around the historical Gasometer in Berlin-Schöneberg. The campus is the setting of an innovative community including applied research, economic and policy consultancies mainly based on the philosophy of sustainability.

3 QUALITY MANAGEMENT

3.1 Process Management

The QMS of the TUB is designed close to the ISO-9001 norm. The relevant processes are available on the website of TUB. In order to evaluate the performance in teaching and learning several instruments are used in our QMS. However, there often is no simple way from check to act, but the results are helpful both for the internal discussion and marketing purposes.

3.2 Graduate studies and impact for the region

Continuous improvement of the curricula was performed by using the results of the quality management instruments. Especially our graduate surveys, which were performed in cooperation with Incher Kassel since 2009 in a nation-wide-project are very well accepted inside the university. The graduates of every year were polled with a detailed questionnaire 1.5 year after graduation. The response rate is usually around 35 % and the results are representative. Current investigations concern the TUB-graduates of the year 2014. Table 1 present some keyfacts for this graduation year.

Table 1: Keyfacts of the graduation survey for the TUB-graduates of the year 2014.

Keyfacts of the graduation cohort 2014	Bachelor degree	Master degree	Diplom degree	TUB overall average
Percentage of female gender	28	30	30	30
Avarage age at time of graduation (years)	25.3	28.1	30.4	27.4
Avarage grade at graduation	2.2	1.7	1.8	1.9
Avarage duration of study (Fachsemester, Median)	8.0	5.0	14.0	8.0
Avarage duration for job search (in months; Median)	2	3	4	3
Average income (pre-tax) per month in € (Median; Only full-time employees)	2,626	3,251	3,251	3,251
Overall satisfaction with TUB (Median 1=very satisfied / 5=very unsatisfied)	2.0	2.0	2.0	2.0
Overall job satisfaction (Median 1=very satisfied / 5=very unsatisfied)	2.0	2.0	2.0	2.0
Number of graduates (N)	**525**	**448**	**200**	**1173**

Both the overall satisfaction with the TUB, as well as job satisfaction at the first job is evaluated good (= 2.0) by bachelor and master graduates. However, the average salary per month in the first year is significantly lower for the bachelor graduates (€ 2,626) compared to the master graduates (€ 3,251). To explain the difference we like to remark that Ba-programs are viewed in the German public sector as leading to second-rank careers ("gehobener Dienst"), whereas Ma-programs lead to first-rank careers ("höherer Dienst"). In the last three graduation cohorts, the salary of the bachelor graduates has increased about € 750 whereas the Ma-value remains constant. This indicates the raising acceptance of bachelor graduates on the job market. In the last four graduation cohorts, the graduates received their first jobs outside university one to three months after graduation. Graduate studies also show the relevance of the graduates for the regional job market. These results are of great importance for the society and the regional government as well. *Fig. 2* shows, that more than 60 % of the TUB-graduates (graduation years 2011, 2012, 2013, 2014 and 2015) find their first job in Berlin. In computer science, nearly 80 %, except in 2015, remain to work in Berlin.

Berlin has become the first start-up city in Germany. 17 % of the German start-ups had their headquarters in Berlin in 2016. Berlin has also the highest foundation rate for start-ups in computer science. In order to strengthen the science in this area, a new centre (Einstein Centre for Digital Future) as a joint venture between Berlin universities and industry with the financial support of the government and the Einstein-foundation has been opened at the 3rd of April 2017 in Berlin. Here, up to 50 new professors in the field of computer science come to the universities and will increase the power of the in this area significantly. The overall funding is € 38.8 million for the next six years.

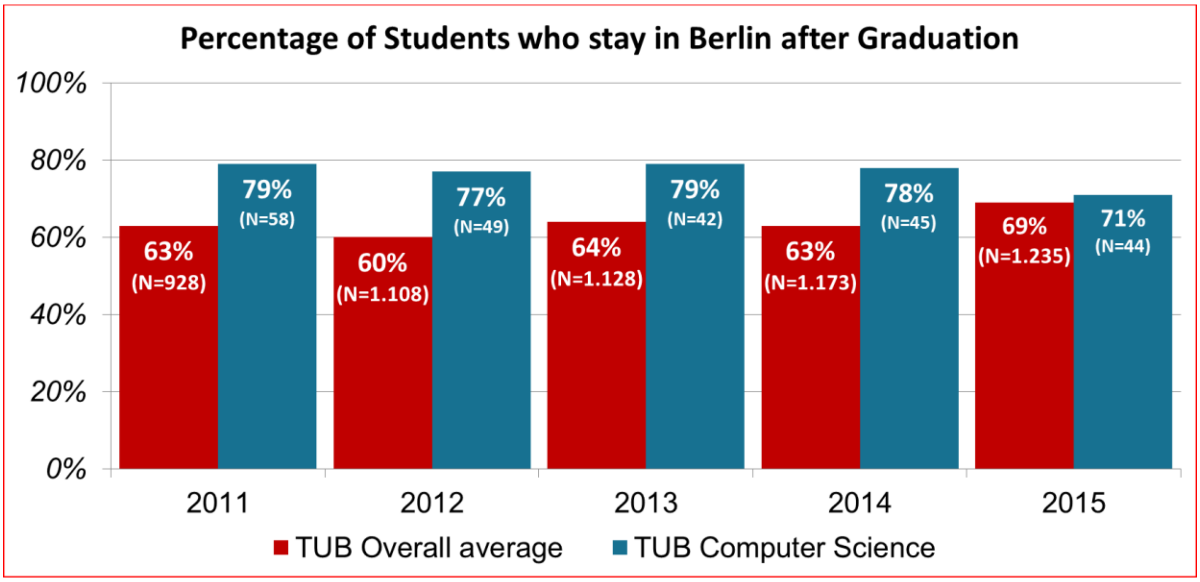

Fig. 2: Berlin as a working place for TUB graduates.

Another fact is remarkable in our graduate studies: 44 % of our graduates could imagine, that they will found their own company in the future. In computer science, the corresponding amount of 61 % is significantly higher. The detailed result for the different disciplines is shown in figure 3.

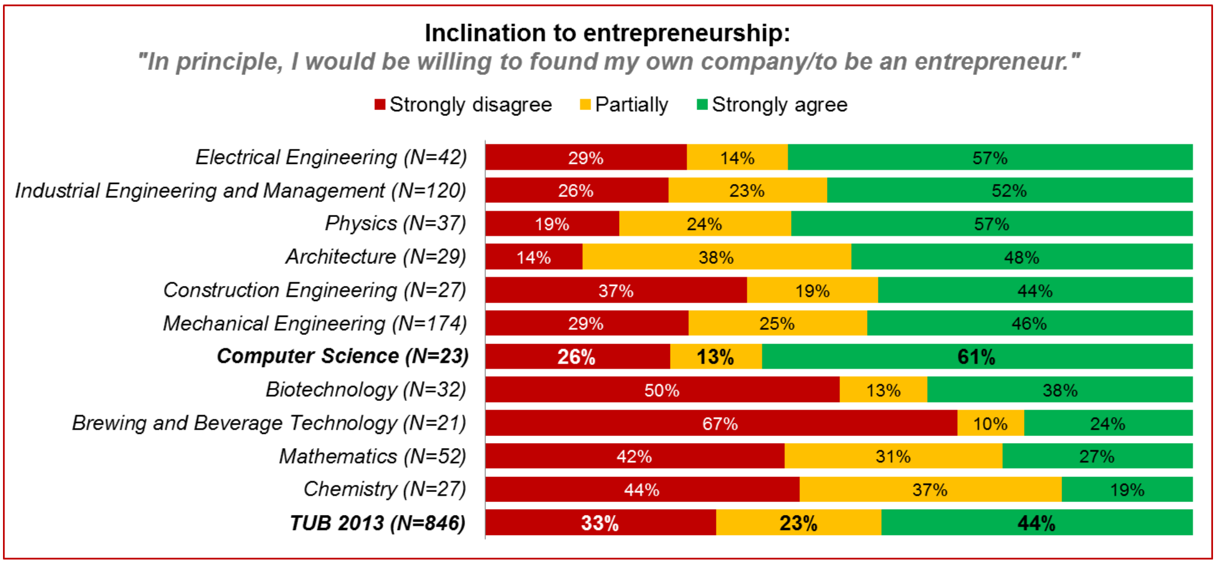

Fig. 3: Inclination to entrepreneurship of TUB-graduates (Graduation year 2013).

Recently, a new study shows the courses offered for the EIT effect entrepreneurial intentions and attitudes significantly positive in only five weeks [4]. It has been proved, that opinion leadership in entrepreneurial related topics positively influences changes in the pro-entrepreneurial intentions. Therefore, we address some of these topics (i. e. start-up science slam, talks by famous founders…) even in the opening ceremony for the new freshman students since 2015. However, we do not have panel studies or tracking which proves the careers of our graduates so far.

4 THE CENTRE FOR ENTREPRENEURSHIP

The TUB aims at profoundly embedding the subject of entrepreneurship in all areas of the university and to make use of the huge potential of commercializing inventions and research results. It´s not surprising that the university decided to do the next step and to concentrate its competencies in research, education and practical entrepreneurship support within the Centre for Entrepreneurship (CfE) which was established in April 2010. The advantage of this new integrated institution is its long-term orientation. Thus, the CfE is financed not only by third-party funding but has also stable financing from university-side. Before designing the TUB CfE programmed, its staff benchmarked successful counterparts at Stanford, the Massachusetts Institute of Technology, Danish Technical University and ETH Zurich. The activities of the CfE are organizationally divided into three main areas: research, education and practice (advice and support). Thereby, the research activities are located at the Chair of Entrepreneurship and Innovation Management. The Founder's Service is responsible for the practical entrepreneurship support of TUB entrepreneurs. The education activities, finally, are coordinated and executed by both the Chair of Entrepreneurship and Innovation Management and the Founder's Service and where described above. The success of the CfE has been measured recently. There are 25 high-tech start-ups per annum in average. More than 70 % of those who have received intensive coaching since 2007 are still in business. The CfE has a great economic impact for the city and beyond: In 2015, 758 spin-off companies run by Alumni of TUB employed up to 20.000 people. The overall turnover was 2.7 billion Euros. Some of the start-ups have direct connection to sustainability topics. On example is the start-up akvola which was founded in 2013. The idea is to make a sustainable sea water treatment. The company receive the ACES Green award and is described in [5]. The "Gründungsradar" an evaluation of academic entrepreneurship sees the TUB on position three out of all larger German universities.

Student Comparative Self-Assessment based on Learning Outcomes

Evaluation of a Stand-Alone Course on Sustainability and Engineering.

André Baier
Lecturer
Technische Universität Berlin
Berlin, Germany
Andre.Baier@tu-berlin.de

ABSTRACT

The on-going evaluation of a stand-alone on sustainability and responsibility at Technische Universität Berlin aims at a comprehensive triangulation of quantitative and qualitative data. This paper will present the core of the quantitative evaluation: A student comparative self-assessment. The students themselves rate their competences on a 6-point Likert scale. The items of this survey are based on the learning outcomes of the course. The assessment takes place either at the beginning (pre) and at the end (post) of the course or as a combined assessment looking back to the beginning of the course (then) and after completing the course (post). The pre-/then-/post-testing results show a significant gain of competences. The described process can easily be adapted which makes this paper relevant for anybody interested in evaluating a course on sustainability and engineering.

Conference Key Areas: Sustainability, Ethics or Engineering Education Research

Keywords: self-assessment, competences, sustainability, ethics, learning outcomes

INTRODUCTION

Education for Sustainable Development (ESD) aims at fostering a generation of active citizens equipped with the tools, knowledge, and experience they will require to induce sustainable changes in both professional and personal contexts [1]. ESD is unique in its quest to ensure graduates to not simply graduate with more knowledge, but newfound competences to embody the traits they value and the capability to act accordingly. In order to be effective within an outcome-based education, competences need to be implemented as learning outcomes. Next, these learning outcomes should be aligned with teaching/learning activities, assessment of students and course evaluation to ensure a coherent teaching/learning experience.

The Blue Engineering Course at Technische Universität Berlin (TUB) addresses the ecological and social responsibility of engineers. Its learning outcomes are based on the concept of Gestaltungskompetenz [1]. Therefore, the learning activities are organized in such a manner that students may acquire competences of an ESD. An effective evaluation of such a course is demanding due to the complex nature of ESD competences and the corresponding activities. This paper will provide a case study on how to describe learning outcomes for such a course and how to evaluate whether the students reach these learning outcomes through a student comparative self-assessment.

1 DESIGN AND CONDUCTION OF THE BLUE ENGINEERING COURSE

The Blue Engineering Course is organized in a highly interactive manner that takes the shift from teaching to learning [2] seriously. Roughly speaking, only one third of the course is conducted by the tutors while two thirds are conducted by the participants themselves. For a successful completion of this 6 ECTS course, the students have to fulfill four assignments: 1) to keep a learning journal [3] over the whole semester; 2) to conduct an existing teaching/learning unit of about 60 minutes length; 3) to develop and conduct a new demanding teaching/learning unit on a topic of their choosing [4]; 4)to document this teaching/learning unit in such a way as to enable others to conduct it.

The fourteen-week course has been first conducted during the winter-semester 2011/2012 with 24 students. From this semester onward, it has been offered every semester, which amounts to a total of 12 semesters and 564 students who participated in it. The number of participants was raised continuously and levels now over last six semesters at about 70 students per semesters. About 31% of the participants study mechanical engineering and about 22% study industrial engineering, where the course can be chosen as an option from a list of compulsory courses. The rest of the students take it as an elective from various study programmes crossing all faculties.

2 LEARNING OUTCOMES OF THE BLUE ENGINEERING COURSE

The description of the learning outcomes of the course follows a design down process, which means that the learning outcomes on the higher educational levels function as guidance on the lower levels [5]. State law as well as various regulations at TUB require that students will learn about responsibility as well as sustainability through various study programmes. Therefore, the described course can easily be integrated into the overall learning outcomes of said university.

For the course itself, two learning outcomes describe what the participants will have learned at the end of the course. These two learning outcomes on the general level of the course are then further ‘designed down’ to be used on lesson level as well as on exercise level. The learning outcomes on the various level have been developed in an open participatory process over the course of five years. The multi-disciplined core team consisted of the professor responsible for the course, two lectures charged with the further development of the course, 8 tutors and many members of the student group that has initially developed the course. Their work was regularly feedbacked by their peers and participants of the course.

2.1 Two Learning Outcomes on the General Level

The two general learning outcomes consider for the individual responsibility as well as the collective responsibility of (future) engineers [6]. Furthermore, the learning outcomes identifies engineers as relevant actors in the democratisation of society nature-relations [7] as well as the general power relations of society [8].

1) The prospective engineers analyze and evaluate the present reciprocal relations of technology, individuals, nature and society by taking different perspectives. Based on this analysis and evaluation, they are able to state their personal perspective and values of the reciprocal relations and act accordingly.

2) The prospective engineers cooperate with others to analyze and evaluate in a democratic process the present reciprocal relations of technology, individuals, nature and society. Based on their analysis and evaluation, they are able to work out a collective understanding with regard to their collective values and democratise the reciprocal relations.

2.2 Twelve Learning Outcomes on Course and Lesson Level

These two general learning outcomes are further design downed by adapting an existing framework of competences of ESD. The concept of Gestaltungskompetenz [1] was chosen over other concepts as it is the only concept that is placed within the broader framework of the set of OECD key competences. It comes with many good practice implementations as it is widely used within Germany where it was used to implement the UNESCO Decade of ESD [1] at the secondary school level. In addition, it is also picked up on an international level in higher education where a trend towards a harmonization of ESD competences is identified [9].

For the design down process, the 12 broadly recognized sub-competences of Gestaltungskompetenz of an ESD [1] have been reformulated as learning outcomes. Next, they were adapted to reflect the two general learning outcomes which let to a total of 12 specific learning outcomes for the Blue Engineering course. See Table 1. These learning outcomes are already specific enough to constructively align with the broad range of learning activities of the course as well as with the formative assessment of the students. Furthermore, this precisoning allows for a comprehensive evaluation of the whole course as described in this paper.

3 EVALUATION OF THE ANONYMOUS COURSE

The Anonymous Course is part of an ESD. As such, it provides a highly demanding and complex learning environment where students have to define and solve problems themselves. Therefore, it does not aim at simple competences that can be assessed in laboratory-like settings where the learning outcome is reached if students would answer, react or behave in one specific way alone and in that way only [5]. If the learning outcomes of a course are competences of an ESD neither one summative assessment, i.e. a multiple-choice test at the end, of the students seems applicable nor one summative assessment. Instead, a comprehensive triangulation of quantitative and qualitative data is necessary to ensure that all aspects of the learning outcomes and therefore all aspects of the 12 sub-competences of Gestaltungskompetenz are properly evaluated. For example, the qualitative evaluation is realized through the analysis of the learning journals as well as through written feedback at the end of particular lessons and at the end end of the course. Among other data acquisitions, a quantitative evaluation is realized through standardised questionnaires for the whole course which is the same for all courses on faculty level as well as the evaluation of particular lessons through questionnaires that are specific to this lesson. In addition, there are two mixed evaluations that are also specific to certain lessons of the Anonymous Course.

Table 1. Gestaltungskompetenz / Learning Outcomes / Questions for Self-Assessment

Sub-Competences of Gestaltungskompetenz (de Haan 2010)	**Learning Outcomes of the Anonymous Course on Course Level**	**Questions for Student Self-Assessment**
OECD - Competence Category - Tools - Using Tools Interactively		
T1 - Perspective-Taking - to gather knowledge in a spirit of openness to the world, integrating new perspectives	T1 - Students take perspectives, change points of view and gather diverse forms of knowledge (i.e. scientific, traditional, common sense) from various actors on the spatial and temporal effects of technology on individuals, society and nature.	T1.1 - argue from different points of view T1.2 - describe the influence of technology on nature and society
T2 - Anticipation - to think and act in a forward-looking manner	T2 - Students anticipate spatial and temporal effects of technology on individuals, society and nature.	T2.1 - consider present and future effects of one's own actions T2.2 - describe the local and global effects of technology
T3 - Gaining Interdisciplinary Knowledge - to acquire knowledge and to act in an interdisciplinary manner	T3 - Students gain knowledge of the reciprocal relations between technology, individuals, nature and society through inter- and transdisciplinary approaches.	T3.1 - find and incorporate knowledge outside of my own discipline
T4 - Deal with Incomplete and Overcomplex Informations - to deal with incomplete and overly complex information	T4 - Students deal with incomplete and over complex information on the reciprocal relations between technology, individuals, nature and society and the risks, dangers and uncertainties which arise from them.	T4.1 - choose an option, although possible consequences are unknown
OECD - Competence Category - Cooperation - Interacting in Heterogeneous Groups		
C1 - Cooperation - to co-operate in decision-making processes	C1 - Students cooperate for a democratic decision-making with regard to process, result and implementation.	C1.1 - reflect upon a group process with respect to process and result
C2- Cope with Dilemmas of Decision-Making - to cope with individual dilemmatic situation of decision-making	C2 - Students cope with dilemmas of decision-making when values and aims are conflicting.	C2.1 - mediate conflicts of goals and values with others

C3 - Participation - to participate in collective decision-making processes	C3 - Students participate at collective decision-making processes.	C3.1 - constructively introduce my point of view in a group discussion
C4 - Motivation - to motivate oneself as well as others to become active	C4 - Students motivate oneself and others to democratize the reciprocal relations between technology, individuals, nature and society.	C4.1 - spread knowledge towards other students C4.2 - prepare a didactical unit on a complex topic
OECD - Competence Category - Action - Acting Autonomously		
A1 - Reflect Principles - to reflect upon one's own principles and those of others	A1 - Students reflect principles which control the reciprocal relations of technology, individuals, nature and society.	A1.1 - know one's own attitude and values towards technology A1.2 - put oneself in the position of others to understand their motives
A2 - Act Morally - to refer to the idea of equity in decision-making and planning actions	A2 - Students identify the underlying values which shape the reciprocal relations of technology, nature, individuals and society and to use them to act morally.	A2.1 - act according to one's own attitudes and values
A3 - Act Independently - to plan and act autonomously	A3 - Students plan independently and act autonomously according to one's own values.	A3.1 - prepare one's own problem statement
A4 - Support Others - to show empathy for and solidarity with the disadvantaged	A4 - Students support others who are disadvantaged due to the dominating design of the reciprocal relations between technology, individuals, nature and society.	A4.1 - identify causes of social inequalities

4 STUDENT COMPARATIVE SELF-ASSESSMENT SURVEY

4.1 Design of the Student Comparative Self-Assessment Survey

A student comparative self-assessment survey is the central part of the quantitative evaluation. For this, each of the 12 specific learning outcomes has been reformulated to reflect a specific part of the course. See Table 1. In addition, to the listed items which were evaluated in every semester, there was a varying set of questions which were used in specific semesters alone. Each item was to be answered on a 6-Point Likert-Scale where students could rate their own competences ranging from 'high' to 'low'. The data collection took place as a classical comparative survey where the students self-assess their competences at two different points in time. In total, five consecutive semesters have been evaluated in this manner from winter-semester 2014/2015 up until the winter-semester 2016/2017. In the first three semesters the surveys were conducted in a pre-post manner, meaning that the survey was filled out in the very first lesson (pre) as well as in the very last lesson of the course (post). For the past two semesters the same items were put into a then-post survey which was filled out at the end of the course. For this, the participants were asked to recall how competent they would judge themselves at the beginning of the course (then) and to judge how competent they are now at the end of the course (post).

4.2 Results of the Student Comparative Self-Assessment Survey

Table 2 shows the major results of the student comparative self-assessment survey. In total, 354 students have successfully completed the Anonymous course in the five evaluated semesters. However, only 216 students have completed the survey at the end of the class, which equals 61%. This discrepancy is due to the fact that the participation in the survey was totally voluntary and that the attendance at the course is generally lower at the end of the semester as students start to prepare for their exams.

Overall, the students judge all of the tested competences much higher at the end of the course than at the beginning of the course. Figure 1 shows the aggregated answers of the pre/then and post survey in a heat map. In addition, this finding is backed up with t-test results usually below $p = 0.01$ which would indicated a significant change. It has to be noted, that the then-post surveys do not show as strong positive gains in self-assessed competences as the pre-post surveys. However, this is in line with other research which stresses the point that then-post surveys might stronger be affected by the impact of implicit theories of change [10]. These quantitative results can also be verified through the qualitative evaluation.

5 CONCLUSION

This paper argues for the adaption of an existing set of ESD competences in a design down process in order to render them useful in a concrete course setting. It further shows how these specific competences can be implemented as learning outcomes. Course specific learning outcomes proved to be helpful for the design of aligned teaching/learning activities and corresponding assessments of students. In addition, specific learning outcomes that are based on competences can also be used for the evaluation of the course itself which may help to reveal if students judge themselves more competent after attending the course.

The workload of the lecturers can further be reduced by conducting the self-evaluation as a then-/post-survey as this type of survey requires only one survey at the end. This method does not endanger the comparative self-evaluation as it also may reveal significant competence gains on the side of the students.

The description of the learning outcomes for the Blue Engineering Course has been a demanding and tiring process. It is has not been concluded yet, as the course itself is continually restructured every semester in order to incorporate new developments and students' feedback. However, so far the description of learning outcomes has been worthwhile as it proved to be helpful not only to reflect upon the course's design and activities but also to evaluate the course accordingly.

Overall, this paper advocates the use of course specific learning outcomes as various synergies may arise which may help to create better and more successful courses.

Table 2. Results of Student Self-Assessment Survey

	2014_2		2015_1		2015_2		2016_1		2016_2		Mean

ABSTRACT

Since gaining independence in 1960, Nigeria has witnessed spiralling engineering infrastructural developments, such as road construction and development of Ajaokuta steel plant and refineries. Nigerian Higher Education Institutions (HEIs) have trained engineers who occupy important engineering posts in the public service and private sectors that administer some of these projects. With Nigeria's ratification of several sustainability pacts, it is pertinent to consider the extent to which sustainability education is reflected in its engineering education. This paper presents a review of Nigerian engineering education based on an analysis of the Benchmark Minimum Academic Standards for Undergraduate Engineering Programmes in Nigeria (BMAS) document issued by Council for the Regulation of Engineering in Nigeria (COREN). The analysis finds that of the 30 engineering programmes listed in the BMAS document, none directly addresses sustainability. The paper therefore highlights the need to mainstream sustainability education into the Nigerian engineering education curriculum. A vital means of achieving such mainstreaming is through the inclusion of a sustainable engineering programme in the BMAS for engineering.

Keywords: Sustainability education, engineering education, sustainable engineering, professional accreditation

INTRODUCTION

The impact of human development on the natural environment has been a cause of increasing concern in recent decades. An important outcome of these deliberations about the environment is sustainable development, which aims to reconcile economic growth and environmental protection. Engineering has been implicated in sustainability crises, including climate change, pollution and resource depletion. Sustainable engineering arose as a strategy to deliver positive engineering solutions and systems to benefit the environment, economy and society. Guiding it is a sustainability worldview which also necessitates sustainability education [1]. As the upshot of international declarations, sustainability education aims to induce in individuals the cognitive orientation needed for an increasingly complex and unpredictable world. The UN Decade of Education for Sustainable Development (UNDESD; 2004-2014) enhanced global efforts to mainstream sustainability education into various higher education institutions (HEIs). In 2004, the engineering education community issued the Barcelona Declaration, actively embracing sustainability education. The Declaration has since underpinned sustainable engineering education worldwide.

Knowledge of sustainability is now a learning outcome of engineering programmes defined by various accreditation bodies including the Engineering Council, UK, the Accreditation Board for Engineering and Technology, USA and the Council for the Regulation of Engineering in Nigeria (COREN). Being a signatory to a number of sustainability-related treaties and resolutions such as Agenda 21, UNDESD and UN 2030 Agenda for Sustainable Development, Nigeria has endorsed sustainability education. Since the colonial era however, Nigeria has engineered many infrastructure such as crude oil refineries, Ajaokuta steel plant, roads, railways, and many residential and office buildings. Nigerian HEIs have produced engineers who administer these projects. Nevertheless, Nigerian engineering education has not been assessed for its sustainability content. COREN, a body tasked with the accreditation of engineering programmes amongst other functions, has developed and issued Benchmark Minimum Academic Standards for Undergraduate Engineering Programmes in Nigeria (BMAS). This document presents an important resource and opportunity for a baseline assessment of the sustainability content of Nigerian engineering programmes.

The purpose of this paper is to appraise Nigerian engineering education with a view to assessing its sustainability content. The paper highlights engineering practice in Nigeria before discussing the education of Nigerian engineers. Nigerian sustainability experience and efforts including sustainability education initiatives are considered. Thereafter, the sustainability content analysis of the BMAS document is presented. Finally, the paper suggests possible sustainability education interventions for Nigerian engineering education.

1 ENGINEERING EDUCATION IN NIGERIA

1.1 Engineering in Nigeria

Engineering in Nigeria evolved as a necessary outcome of colonialism. Engineering activities were undertaken to advance the goals of colonialism centred on governing Nigerian territories [2]. Road and railroad construction, water supply, mining, dredging, housing, electrical and mechanical works featured prominently amongst recurrent projects in colonial Nigeria. The engineering legacy bequeathed to Nigeria by the British continued without much change. Indigenisation efforts progressed very slowly as British and other foreign engineers continued to direct various engineering works across the country. Over the years, Nigeria took full ownership of engineering practice in the country. Professional associations emerged including Nigerian Society of Engineers, COREN, and Nigerian Academy of Engineering. These organisations acted as consultants to successive Nigerian governments and to the academia broadening the purview of engineering knowledge and ensuring professionalism. Engineering in Nigeria now occurs within the structure of governmental regulation and professional associations' guidance. Only registered engineers are legally allowed to practice engineering in Nigeria. Thirty engineering fields are presently recognised in Nigeria [3].

1.2 Educating Nigerian engineers

At independence in 1960, Nigeria had an educational system modelled on the British framework. Since then, successive Nigerian governments have made efforts to modify the colonial legacy for more effective and meaningful outcomes. Higher education institutions (HEIs) grew from only 2 technical colleges in 1944 to a total of 143 in 2016 comprising 40 federal universities, 42 state universities and 61 private universities [4]. Today, the Federal Ministry of Education (FME) has the mandate to formulate and oversee enactment of national educational policies. Educational policies formulated by FME shape the route to an engineering career in Nigeria. Students desiring to study any engineering field are required to take such science subjects as mathematics, physics, and chemistry at senior secondary level. A minimum of credit score in these subjects and in two others including English Language at the West African Examination Council-conducted examinations or the national equivalent is mandatory. Initially modelled on the British system that operates a 3-year programme, engineering degrees in Nigeria are now acquired over a 5-year period. General physical and chemical science subjects accompanied by one or two social science subjects including Use of English are taught to first- and second-year engineering students. Students are progressively exposed to the core of their chosen disciplines over the next 3 years. A compulsory industrial work experience scheme is sandwiched in the engineering programme. In the final year of their programme, engineering students undertake a research project either individually or collaboratively under the supervision of an academic. A Bachelor of Engineering or Bachelor of Technology in Engineering is typically awarded upon successful completion of the 5-year programme.

2 SUSTAINABLE DEVELOPMENT IN NIGERIA

2.1 Nigerian sustainability experience and response

Nigeria's interest in sustainability was piqued by an environmental disaster in 1987 in which about 4000 tonnes of toxic waste originating from Italy were deposited in Delta State. This incident prompted the enactment of Federal Environmental Protection Agency (FEPA) Decree and Harmful Waste Decree in 1988 proscribing dumping and trafficking in toxic wastes across Nigerian territorial boundaries including its Exclusive Economic Zone. The FEPA Decree led to the formation of an environmental agency tasked to protect and manage the environment. In 1999, the Federal Ministry of Environment (FMEnv) was established to coordinate all environmental matters. FEPA metamorphosed into National Environmental Standards and Regulations Enforcement Agency in 2007 and was subsumed by FMEnv. With a vision "to ensure a Nigeria that develops in harmony with the environment", FMEnv has engaged in a number of sustainable development efforts [5]. Sustainable development concerns in Nigeria have followed the typical sustainability ideas' pattern of percolation into societies in which social and economic dimensions are preceded by the environmental component. Following its participation at the United Nations Conference on Environment and Development in Rio de Janeiro in 1992, Nigeria attempted to implement the outcome of the summit by drafting Nigeria's Agenda 21. In response to the emergence of MDGs in 2000, Nigeria created the Office of the Senior Special Assistant to the President on MDGs [6].The expiration of MDGs in 2015 ushered in the UN 2030 Agenda for Sustainable Development comprising 17 Sustainable Development Goals which Nigeria endorsed. Given the abysmal outcome of Nigeria's MDGs efforts, speculations are rife that the Sustainable Development Goals may not fare any better.

2.2 Nigerian sustainability education

Allusions to education in several sustainability-related documents such as Nigeria's Agenda 21 are either in reference to "education for all" or to "environmental education". Given such impression, Nigerian educational system has responded to sustainability education with chiefly environment-related courses. Lessons on such environmental subjects as natural resources, sanitation, and pollution permeate Nigerian primary education. The secondary schools are introduced to some relatively advanced environmental issues such as waste and land pollution, ecology and water pollution. The HEIs offer a variety of degree level environmental courses titled variously as *environmental engineering*, e*nvironmental management, environmental technology* and e*nvironmental resources management.* Sixteen Nigerian universities currently run these courses [7]. Sustainability education in the strict sense of Education for Sustainable Development (ESD) has not gained much recognition in the Nigerian educational system. Nigeria has no explicit sustainability education framework and there is no Nigerian HEI that offers a sustainable engineering degree, course or module[2]. This absence of active ESD programmes in Nigeria is corroborated by a study that finds sustainability education to be slowly evolving in Africa [8]. The UNDESD Final Report suggests that "sustainable development is only an emerging interest among African HEIs" [9]. The prospect of an accelerated uptake of sustainability education in Nigeria has equally not been realised even with the existence of 4 UN-established Regional Centres of Expertise (RCEs) on ESD in the country. Although appreciable progress has been made in terms of the informal and non-formal ESD components, the formal element is inadequately attended to [10]. Contributing to this undesirability is the failure of the RCEs to successfully network with Nigerian HEIs thereby fragmenting the ESD initiative. Renewed networking is required to mainstream ESD into Nigerian HEIs. An important means of achieving such nexus is through FME, FMEnv and other HEIs stakeholders including COREN and National Universities Commission.

3 SUSTAINABILITY ASSESSMENT

Sustainability assessment in HEIs has been undertaken since the emergence of sustainability education. Several sustainability assessment tools have been developed to evaluate the sustainability efforts of various HEIs around the world. A number of these tools generally assess sustainability initiatives in the customary HEI functions of education, research, community outreach, and university operation [11]. However, some of the assessment tools focus exclusively on curriculum with sustainability content having a central importance.

3.1 Sustainability content

What qualifies as sustainability content is an important question in sustainability assessment research. The defining principles of sustainability have rightly guided most assessment tools. However, as sustainability concept is highly fluid, these principles are somewhat difficult to pin down. Hence, various measures of sustainability content in curriculum exist. The point of departure for most researchers is the use of expert-

[2] This is based on the Joint Admissions and Matriculation Board Brochure which contains all the courses offered in Nigerian HEIs.

derived sustainability themes which allows curricular sustainability content to be measured in terms of the spread of these themes. An example of such approach is the Sustainability Tool for Assessing Universities Curricula Holistically made up of 40 sustainability topics under the 4 categories of environment, economy, society and crosscutting themes [12]. Sustainability content can therefore be considered as the spread or coverage of sustainability topics or ideas in a curriculum highlighting the interdependence of environment, economy and society along with the multidimensional problem-solving strategies for addressing sustainability challenges. This operational definition guided the documentary analysis of the BMAS document.

3.2 BMAS document

BMAS is a document issued and reviewed episodically by COREN to set out standards for running undergraduate engineering programmes in Nigeria. A 367-page document containing over 100,000 words, the BMAS lists 30 approved engineering programmes with a description of all required courses for each programme. The scope of each course details prerequisite and co-requisite topics as well as admission requirements and list of laboratory equipment. Common engineering courses are equally detailed. The document is divided into 3 parts including general requirements section, specific requirements subdivision and accreditation score sheet. The BMAS is an outcome of deliberations by engineering practitioners and academics in Nigeria. Deans and heads of engineering departments from Nigerian universities as well as COREN management are involved in the development of the document. Each Nigerian HEI submits syllabus of its engineering programmes highlighting course contents, philosophy, and minimum facilities. A workshop is held to deliberate on these submissions. Courses are included in the BMAS on the basis of global best practice and contextual relevance. The BMAS standardises the syllabi and becomes the official guideline for all undergraduate engineering programmes in Nigeria. The preamble of the BMAS itemises 9 learning outcomes for engineering programmes. Item 6 states that "a graduate of an engineering programme accredited by COREN is expected to have *ability to consider the environment and sustainability in finding solutions to problems*" [3]. An interesting fact about the BMAS is that it informs all handbooks of engineering faculties in Nigerian HEIs. Furthermore, Nigerian HEIs refer to the BMAS for purposes of accreditation and curricular development. The BMAS is the basis upon which COREN accredits engineering programmes. The mention of sustainability as a competence expected of engineering graduates is, therefore, reassuring. However, this can only be effective with an actual integration of sustainability education in the programmes. The BMAS documentary analysis set out to discover if such alignment exists.

3.3 Analysis procedure

The question that informed analysis of the BMAS is whether or not sustainability topics are covered in the document. It was therefore of interest to analyse the mentions of a sustainability topic or idea in any engineering programme. The documentary analysis involved the use of NVivo 11. The BMAS document was converted to an editable PDF form and uploaded into the NVivo 11 software. Thirty engineering programmes listed in the BMAS with preamble and common engineering courses formed a total of 32 cases. A priori codes based on 4 categories of environmental concepts, economic concepts, social concepts, and multidimensional concepts became parent nodes. In line with the classification of Sustainability Tool for Assessing Universities Curricula Holistically, the environment node had 9 child nodes each being an important environment topic. Similarly, economic topics gave rise to 6 child nodes under the economic parent node, while the social parent node had 12 child nodes derived from myriad social issues like poverty, etc. The multidimensional node contained 10 child nodes based on a range of crosscutting themes such as systems thinking, etc. The entire document was then scrutinised and coded at the cases and nodes. Words such as 'sustainable' used in the literal sense were not coded. Topics had to clearly embody sustainability ideas before being coded.

4 BMAS SUSTAINABILITY CONTENT

The analysis shows that the BMAS document has an extremely low sustainability content. Contained in merely 2% of the entire document, sustainability topics have not received much attention in Nigerian engineering programmes. Compared to 2 common engineering topics, namely engineering materials and engineering mathematics, which both cover nearly 5% of the BMAS, the 37 sustainability topics assessed in this study are poorly featured. Nonetheless, from Figure 1 and Table 1, economic and environmental concepts are featured in the BMAS document more than the social and multidimensional themes.

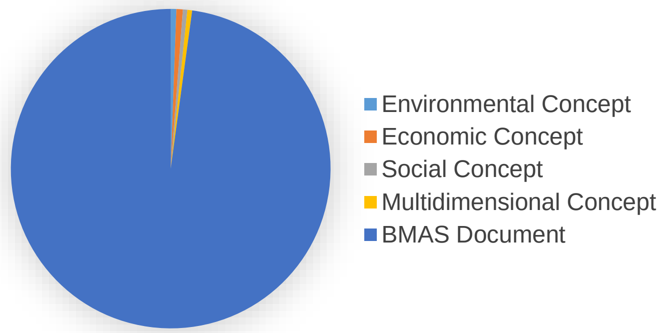

Fig 1. Spread of sustainability concepts across BMAS Document

Table 1. Sustainability coverage

Sustainability Concept	Coverage
Environmental	0.57%
Economic	0.65%
Social	0.45%
Multidimensional	0.48%
BMAS Document	97.85%

4.1 Environmental and economic contents

Figures 2 and 3 show the distribution of environmental and economic concepts across the engineering programmes in the BMAS document. Eleven programmes feature at least one environmental topic with Environmental Engineering containing 4 topics. Four environmental themes are completely absent in all of the programmes. Similarly, only 12 programmes cover economic topics and 2 economic themes, namely GNP and 'Accountability' are not mentioned in any of the programmes.

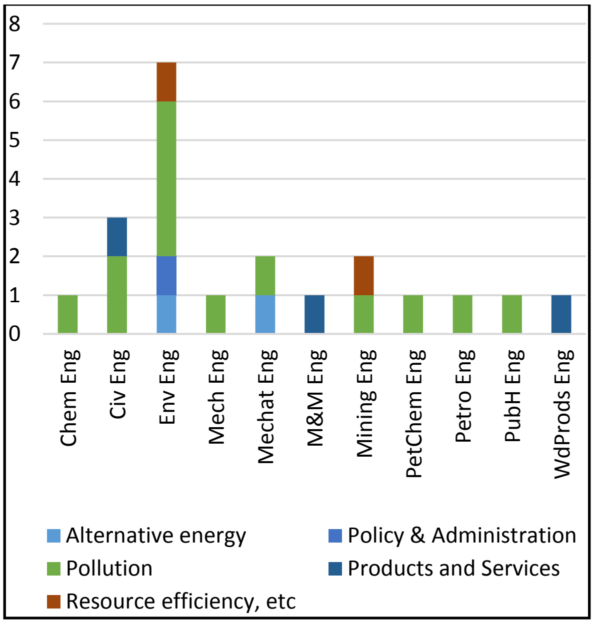

Fig 2. Environmental Concepts Distribution

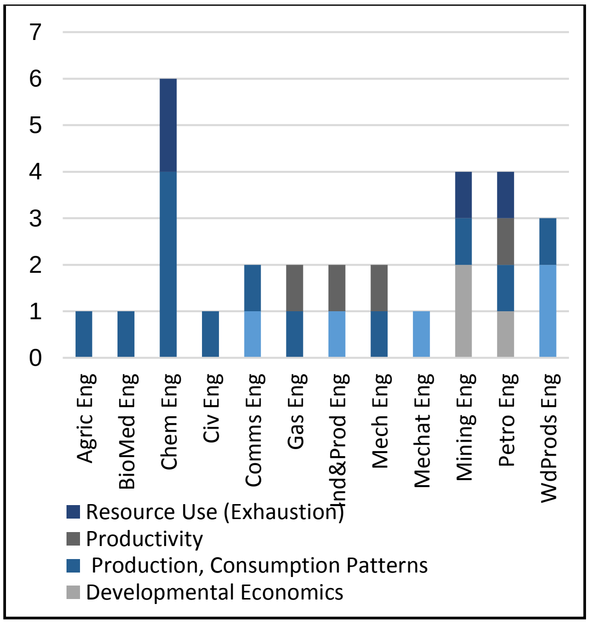

Fig 3. Economic Concepts Distribution

4.2 Social and multidimensional contents

Figures 4 and 5 present the spread of the social and multidimensional concepts in the engineering programmes. Whilst 9 programmes feature some social concepts, only 7 programmes mention at least one multidimensional theme. Equity and justice, long-term thinking as well as communication and ethics/philosophy are covered in the common engineering courses. Eight social and 6 multidimensional themes do not feature in any of the courses.

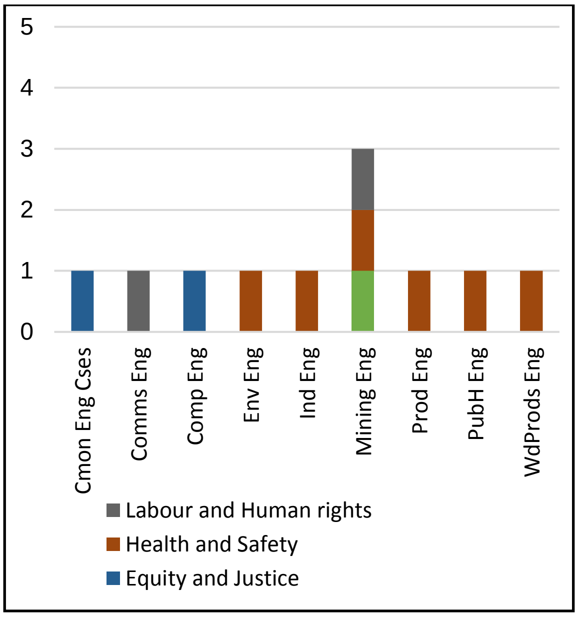

Fig 4. Social Concepts Distribution

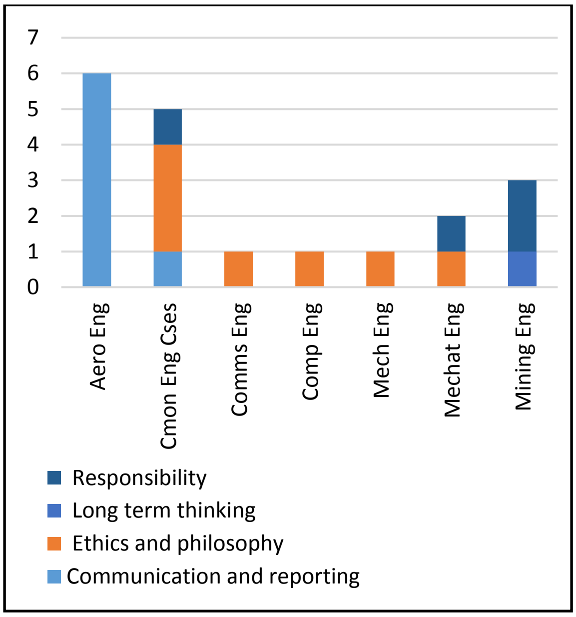

Fig 5. Multidimensional Concepts Distribution

5 SUSTAINABILITY EDUCATION INTERVENTION

The trajectory of engineering and sustainability in Nigeria is dotted with episodic interventions. Consequently, an education intervention to accommodate sustainability topics in the BMAS document is appropriate. The BMAS documentary analysis reveals dissonance between the required learning outcomes for engineering programmes and the imperative of sustainability education. Sustainability expertise has been clearly identified as a skill required of all engineering graduates, but the BMAS document shows no evidence of concrete sustainability education. Evidently, no engineering programme directly addresses sustainability. A possible intervention could be the substitution of the common engineering courses with sustainable engineering modules. Since the common engineering courses already feature some sustainability themes, albeit inchoately, sustainable engineering can aptly subsume these courses and give them the necessary sustainability finesse. Alternatively, COREN could insert in the BMAS a course entitled *Introduction to Sustainable Engineering* which could be made a core requirement from the third year onwards. This is because the third year marks the beginning of core courses for students of all engineering disciplines. Thus, beginning this stage with a sustainable engineering course could be an immensely effective sustainability education strategy. Such approach would ensure that sustainability eventually features in the final-year projects of engineering students.

6 SUMMARY

Engineering and sustainability education in Nigeria are as yet not properly aligned. Engineering has been practised in Nigeria since the colonial era. Nigerian engineers are trained in various HEIs across the country. The imperative of sustainability education suggests a complex dimension for Nigerian engineering education. In spite of being a signatory to many sustainability pacts and its experience of an environmental disaster, Nigeria has no sustainability education framework. This paper appraised Nigerian engineering education and assessed its sustainability content based on the BMAS document. The paper highlighted engineering practice in Nigeria and discussed the education of Nigerian engineers. Nigerian sustainability experience and efforts were examined. Thereafter, the sustainability content analysis of the BMAS document was presented. Finally, the paper suggested possible sustainability education interventions for Nigerian engineering education.

ABSTRACT

Since the publication of the UN-sponsored World Commission on Environment and Development report [1] in 1987, thousands of initiatives have been undertaken to address the different aspects of environmental challenges [2]. Among these initiatives, in 2002 the UN General Assembly proclaimed the UN Decade of Education for Sustainable Development, 2005-2014, 'emphasising that education is an indispensable element for achieving sustainable development'.

Sustainability has been on the agenda of many engineering faculties since the late 1990s [3]. It has become clear that “a new kind of engineer is needed, an engineer who is fully aware of what is going on in society and who has the skills to deal with societal aspects of technologies” [4]. Literature covering this topic is abundant. The discussion on how sustainability can be successfully integrated into engineering programmes is still receiving attention.

This paper aims to present a literature review focused on sustainability in engineering education. The review is based on the Systematic Literature Network Analysis (SLNA), a methodology including a collection of computer-based tools that analyses bibliographic data, and that have been applied to the continuous improvement of Higher Education [5]. The SLNA is adopted in this work in order to unfold the dynamics of sustainability in engineering education and identify the directions in which engineering faculties are moving.

Conference Key Areas: Sustainability and Engineering Education; Curriculum Development; Engineering Education Research.

Keywords: Sustainability development, education, curriculum development, Systematic Literature Network Analysis.

1. INTRODUCTION

The first definition of sustainability development was given by World Commission on Environment and Development (Brundtland Commission) in 1987 and states that sustainability development is the "development that meets the needs of the present without compromising the ability of future generations to meet their own needs”. To pursue this policy, Education on Sustainable Development (ESD) was recognised by the United Nations Economic Commission for Europe (UNECE) to play a major role in this process. ESD is a main activity of UNECE, which, together with the United Nations Educational, Scientific and Cultural Organisation (UNESCO), implemented a road map for ESD in 2005. The road map consisted of three steps: Phase I (2005-2007), i.e. Stocktaking, where the Member States had to identify existing initiatives; Phase II (2008-2010), i.e. Integration, where the Member States had to begin the integration of SD in the curricula; Phase III (2011-2015), i.e. Implementation, where the Member States had to ensure the introduction of ESD in every school and promoting teachers’ education.

The final comment in the report published after the end of Phase III (May 2016, [6]) was that “significant advancements have been made on four of the seven Strategy issue areas: *policy integration*, *curricula*, *tools and resources*, and *cooperation and networking*” but “more systematic attention should be given to progress on non-formal and informal learning, and special consideration given to advancing ESD research, monitoring and evaluation as essential inputs to strengthening ESD”.

Hence, in order to contribute to advancing ESD the goal of this paper is to depict a landscape of the scientific literature on SD in the curricula of engineers through the adoption of the dynamic literature review method called “Systematic Literature Network Analysis (SLNA)”. This method was introduced by [7] and combines the systematic literature review approach with bibliographic network analyses. The successful adoption of such an approach to other contexts, e.g. [8], [9], [10], proves its potential value in the identification of research trends and evolutionary trajectories.

2. Material and methods

SLNA starts with the application of a systematic procedure (Systematic Literature Review, SLR) to identify and select relevant papers. Then, the selected papers are analysed using bibliometric tools, such as the Citation Network Analysis (CNA) that provides information on the evolution of the more active research areas; the citation is assumed to represent the influence of the cited work on an author’s new work [11].

The first phase, i.e. SLR, includes the following steps: *scope of the analysis*, to define the boundaries of the study; *locating studies* to retrieve papers form databases through keywords, search strings and other criteria (e.g. type of document, time window); *study selection and evaluation*, to isolate the most relevant papers.

The second phase of SLNA takes into account the papers selected in the first phase and applies bibliographic network analyses and network visualisation tools.

Nevertheless, delineating and representing a research field only by means of papers linked by citations may lead to biased results since some important contributions, even if their content is relevant, may be not yet cited due to various causes. For this reason, the results of citation network analysis is combined with those provided by other bibliometric tools.

Papers were collected from the Scopus database, which is, together with Web of Science (WoS), the most commonly used scholar citation database. Scopus is very similar to the WoS database but Scopus has a wider coverage [11]. To build the citation network VoS Viewer (http://www.vosviewer.com/, [31]), a software package able to analyse bibliometric networks, was adopted. The citation network was then studied using Pajek [13] which is a software package for Social Network Analysis.

3. First phase of SLNA methodology: SLR

3.1. Scope of the analysis

As mentioned in the introduction, many efforts have been made by international organisations to introduce SD concept into the educational curricula. The scope of the analysis of this paper is to find research directions in the field of engineering education on SD and to understand if the interest of international organisations was reflected in the content of the papers analysed.

3.2. Locating study

For locating the study it is necessary to define some keywords. The keywords were discussed with a panel of experts composed of mechanical and environmental engineers. It is important to underline that this step of the analysis is very critical to reduce the individuals' bias. The final search string used in Scopus is as follows: 'curricul*' AND 'development' AND 'sustainability'. This was searched in the field "keywords", which includes author keywords and keywords assigned by Scopus and the Engineering area was selected.

3.3. Study selection and evaluation

The search was performed on April 2017, without any restriction on document type (conference paper, article, review, article in press, letter) and on time window (the first document dates to 1990): 267 documents were retrieved.

4. Second phase of SLNA methodology: bibliographic network analyses

The works identified in the first phase were used as input for the second phase of SLNA. A local analysis using citation network was performed to detect the evolution of the main concepts. Some of the 267 papers may be not included in the citation network but cited many times in Scopus and then a complementary analysis of the most cited papers in 2016 in Scopus was performed.

4.1. Citation Network Analysis (CNA)

To perform CNA it is firstly necessary to exclude the isolated nodes that are papers nor cited neither citing others in the network. This is the case of 188 documents. The remaining 79 documents form connected components. In details, 68 documents form a big connected component and the remaining papers are connected in other four small components. The amount of information that can be extracted from the biggest component is more structured than the one emerging from small components with only a very limited number of connected nodes [10]. Based on this consideration, only the connected component with 68 documents will be analysed.

4.1.1. The analysis of the Biggest Connected Component

Figure 1 depicts the biggest connected component. To analyse this component the Main Path (MP) algorithm [12] was used. MP extracts main trends in the evolution of paper contents identifying papers that constitute part of the backbone of the research tradition. This backbone is composed of papers lying on the shortest paths between source and sink nodes. A source is a paper cited by but not citing other papers of the network while a sink is a paper citing but not cited by other papers of the network.

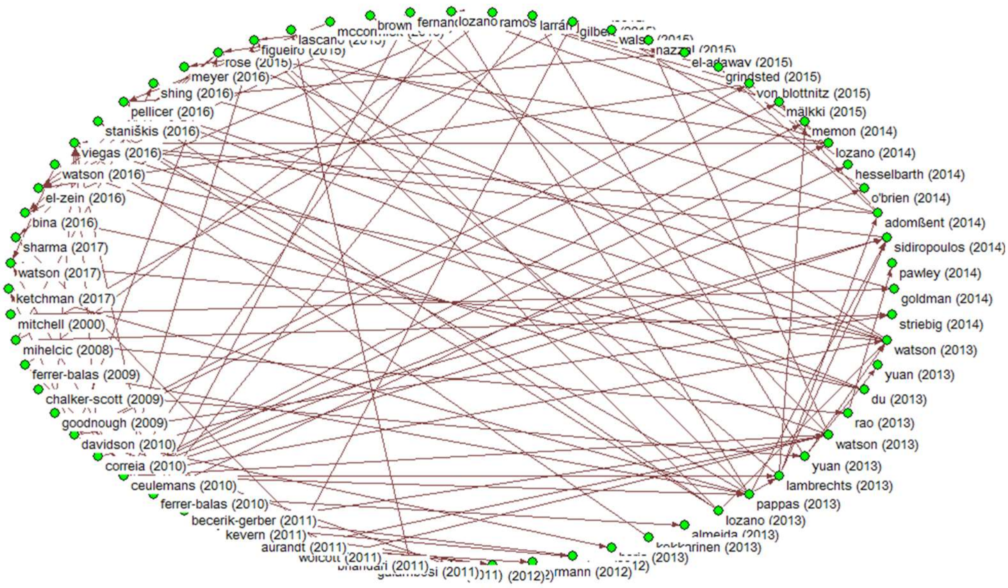

Figure 1. The biggest connected component of the citation network.

In [14] it has been observed that the MP obtained in this way provides the most significant path. Nevertheless, if a discipline has many sub-areas, this is not enough to uncover all the milestones of the research tradition. [14] propose to relaxe some constraints of the process to build the MP to generate the so-called *key-route*. In Figure 2 the *key-route* of the biggest connected component is presented. The papers range from 2009 to 2017 and the flow of knowledge shows a change in the research interests in engineering education on SD, starting from the need to present a systemic and holistic vision of SD passing through the development of instruments helping to develop a curriculum to arrive, recently, to the development of measures to quantify the SD content of curricula or to quantify learning outcomes related to SD.

- *The need for a systemic vision of sustainability development.*
  [15] suggested to involve external stakeholder in the curriculum development; [16] observed that SD in engineers' curricula helps students to think using system theory perspective including social, environmental, economic and technical aspects. [17] stated that the competencies on sustainability, provided by many courses, are fragmented and this calls for adjusting programmes of study to embrace a system thinking approach. A holistic approach is highlighted by [18] too, which suggested introducing geography in the SD curriculum due to its strong tradition within the human-environment theme.
- *Instruments helping the integration of sustainability development in the curriculum.*
  [19] proposed a very accessible teacher's manual for SD integration. [20] presented a process for developing a curriculum in Engineering for SD. They succeed to represent and integrate different courses using Concept Maps and 'Sustainability Tool for Assessing Universities' Curricula Holistically" (STAUNCH). [21] proposed a web-based sustainability portal to support curriculum renewal based on a sequence of workshops and meetings that help teachers to meet the needs of students.

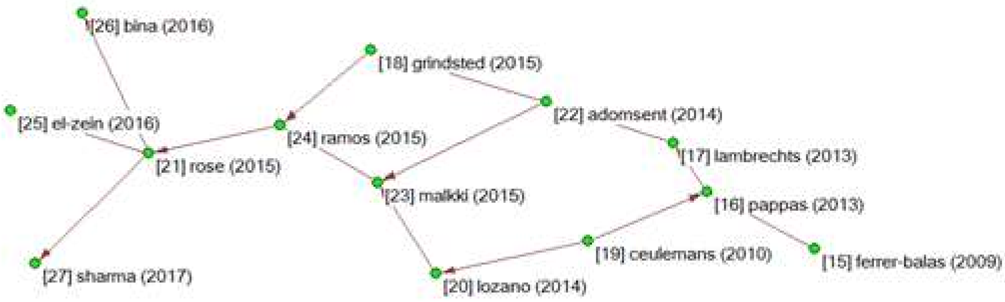

Figure 2. The *key-route* of the biggest connected component.

- *Necessity to quantify the learning outcomes and the content of curricula* .
The importance of quantifying learning outcomes was underlined by [22]. [23] proposed an index (Relevant Ratio) to measure the amount of content on SD of curricula. This ratio indicates the weight of sustainability topics in a programme.

Morever, the necessity to organise the works on the curricula on SD is shown by [24] where 33 papers on curriculum development in higher education institutions are commented; [25] demonstrated that an approach to engineering education strongly based on problem-solving is an obstacle for a complete understanding of SD; [26] analysed 25 top master programmes worldwide for urban development; [27] proposed a mixed approach based on qualitative (thematic groups) and quantitative (survey pre and post assessment) techniques in a multidisciplinary class of students. The methodology was tested and the advantages and disadvantages presented.

The research directions identified in the *key-route* works have been then compared with the aim of the UNECE initiative, to understand their degree of alignment even if none of the papers was funded by this framework. Results are shown in Table 1.

Table 1. Comparison between the UNECE initiative and the research directions identified in the *key-route*.

Time window	UNECE Phases	***key-route*** **Papers**
2005-2007	Phase I. *Stocktaking*: the Member States had to identify existing initiatives;	
2008-2010	Phase II. *Integration*: the Member States had to begin the integration of SD in the curricula;	The necessity of a systemic vision and the stakeholders' involvement [15]. Development of instruments for the integration of SD: a teacher's manual [19] . A method for developing a curriculum in SD engineering [20].
2011-2015	Phase III. *Implementation*: the Member States had to ensure the introduction of ESD in every school and to promote teachers' education and measuring the outcomes.	Necessity to quantify the learning outcomes and the curricula contents ([22], [23]). Obstacles to the implementation of the ESD [25].

In particular, it is interesting to observe that during Phase II (i.e. Integration), some papers were published on practical tools for the integration of SD into curricula, while during Phase III (i.e. Implementation) papers related to quantifying learning outcomes, content and implementation obstacles appear ([22], [23] and [25]). It is possible to conclude that the UNECE initiative, reflected in many national initiatives, influenced research directions in the engineers' curriculum development on SD.

4.2. Global Analysis

As mentioned, it is necessary to cross the information provided by citation network with a global analysis. The first step consists in analysing all the papers from the point of view of distribution over time, authors and journals. In Figure 3 the 267 papers by year of publication are represented. A fast increase starts after 2007 and this is interesting in the light of the efforts of the international organisations after 2005. The number of works seems to reach a plateau around 2014 (data on 2017 is partial). Most of the works are conference papers or articles. The most productive authors are Lozano R. and Ceulemans K. who authored/co-authored many papers of the *key-route* too. Another author appearing in the *key-route* is Ferrer-Balas D. who wrote the oldest paper of 2009, which seems a milestone of the research tradition. The journal more often publishing papers on this subject is *Journal of Cleaner Production.* Also all papers on the *key-route* are published in this Journal.

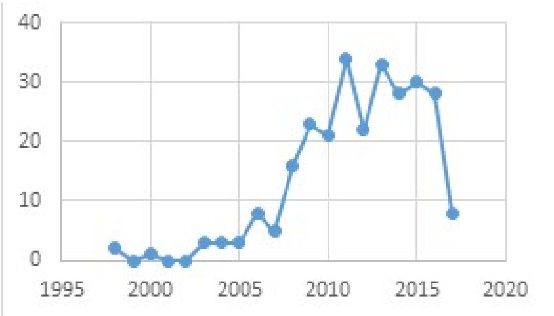

Figure 3. Number of works published over time.

.

Another shortcoming of the citation network and of the *key-route* is their inability to isolate papers gaining attention recently, since they did not have time to be cited or because they are cited by papers not included in the connected component. In Table 2 the ranking of the most cited papers in 2016 is provided together with the evolution of the number of citations they received in Scopus over time.

Table 2 - Ranking of the top cited papers in 2016.

Rank	Publication year	Reference	Part of the connected component (CC) and Key-Route (KR)	2010	2011	2012	2013	2014	2015	2016	2017
1	2011	[28]	CC	0	2	5	13	6	11	12	0
2	2013	[29]	isolated node	0	0	0	1	6	0	10	2
3	2010	[30]	CC	1	2	3	21	7	17	8	2
4	2014	[22]	CC and KR	0	0	0	0	0	7	8	5
5	2015	[24]	CC and KR	0	0	0	0	0	0	8	4
6	2010	[19]	CC and KR	0	2	1	10	7	17	7	2

Among the top six papers, three belong to the connected component and to the *key-route*. The first three works ([28], [29], 30]), although not very recent, seem to have recently acquired interest and this deserves special attention. [28] studied, using a survey, the introduction of Building Information Modeling and sustainability in the Architecture, Engineering and Construction (AEC) curricula. The importance of education on SD for civil engineering it is not a new theme but it is recently gaining more importance due to the fast development of new materials and technologies and the related employment opportunities. [29] proposed a new methodology for the introduction of SD in the curricula of the energy engineers using multimedia internet-based technology. [30] is a review of the papers presented at the 5th Environmental Management for Sustainable Universities, an international conference held in 2008 in Barcelona (Spain). Some of the top ranked papers are literature reviews (traditionally receiving many citations) but the presence of [28] and [29] showed the higher level of importance of SD for AEC and Energy engineering than for other areas.

5. SUMMARY

In this paper we have applied SLNA to perform a literature review of the research on the introduction of SD in engineers' curricula. The necessity to perform research and develop tools to this end is recognised and fostered by UNECE. The analysis using citation network highlights an alignment between research directions and the UNECE initiative, i.e. the implementation of tools to help teachers to introduce SD in the curricula and the development of new measures to quantify the SD content of curricula or to measure the learning outcome.The ranking of the most cited papers in 2016 pointed out two additional papers not included in the *key-route,* which show a great interest in the introduction of SD especially in curricula of energy engineers and AEC. This can be due to the fast development of new material and technologies and the employment opportunities in these areas. Hence the importance to pay attention to SD becomes even more important. Nevertheless, even if this analysis shows the general importance to introduce SD in the engineers' curricula, it seems that efforts have concentrated mostly on some specific areas (AEC and energy) while other areas seem overlooked (e.g. industrial ([32],[33]) or electronic engineering). As [25] point out, "a deeper change in the engineers' vision is necessary to change their mode of engagement with the world and their ability to tackle root causes of social and environmental issues in technologically advanced society".

ABSTRACT

Sustainability, social and environmental responsibility become more and more relevant for professional engineering. This is recognized by universities that are doing their best to introduce these issues in the curricula. But this is not a trivial issue and their integration with the existent and news issues must be total. So, a lot of authors, academics, researchers are always concerned with this and are trying different approaches and learning methodologies in order to achieve successfully sustainability integration. This paper presents and explores some of these approaches and perspectives from four different countries: Portugal, Brazil, Canada and Spain. The study is based on the analyses of papers, presentations and debate session results from a previous engineering education conference. In spite of the reduced sample, it was a lived sample that shared personal and team perspectives about the issue through the debate. Also, it is discussed how the participants introduced sustainability, corroborating that this integration could be an achievable outcome and not a utopia.

Conference Key Areas: Sustainability, Engineering Education, Research
Keywords: Sustainability, Engineering Education

INTRODUCTION

Pappas [1] defined a sustainable society as *"A sustainable society possesses the ability to survive and prosper, not just with respect to environmental resources, but also with respect to quality of life as it pertains to social, economic, technical and individual contexts, and especially the values and conditions that promote continued human prosperity and growth (…). A sustainable society meets these needs simultaneously,*

[1] Corresponding Author
A. C. Alves
anabela@dps.uminho.pt

and in the context of human respect and the ability to negotiate differences without violence.".

The same author [1][2], assuming that individual sustainability dimension is probably the most influential factor in the success of activities in other dimensions of sustainability, proposed that the individual's understanding of the complexities and interconnections between their own sustainability contexts is necessary to further understanding of the community and global sustainability. Thus, the promotion of true learning about sustainability is, firstly, to develop in these individuals the understanding and appropriation of the values of individual sustainability and the ability to change oneself intentionally.

In this sense, universities have a significant role in promoting the Sustainability concept in its different spheres: teaching, research, extension, and management. In fact, Education for Sustainable Development (EDS) has been on the agenda of many universities especially promoted and guided by the Decade of Education for Sustainable Development (DESD) (2005-2014) [3], which was completed with some achievements and its follow-up, the Global Action Program (GAP) on EDS [4].

Universities have begun the way to ESD, but there are still new concepts in most universities [5–7] or they are far from a complete integration into university operations and curricula [8–10]. Only 15 of more than 14,000 universities worldwide have published their sustainability reports [11]. However, as it has been shown, it is accepted that education is a key element in the change and transformation of behavior and practices towards a sustainable society [12].

Attending to this context, the main objective pursued by this study was to analyze different approaches towards Engineering Education for Sustainable Development (EESD) from different countries and contexts presented in a real and live debate session of a previous Engineering Education conference. Also, in this paper are presented the results of the discussion among the authors of the proposed approaches and others participants in the debate session. As a secondary objective was expected to answer or contribute to the answer or make deeper questions about future challenges in a real implementation of EESD based on real case studies.
This paper is divided into five main sections. After this introduction, a brief literature review is presented. The research methodology is presented in the second section. The study context is presented in section three. A debate to discuss the sustainability theme in engineering curricula took place in this study context which main results are highlighted in the fourth section. Finally, conclusions are drawn up in section five.

1. BRIEF LITERATURE REVIEW

Attending to the sociocultural complexity in which we live and the multiplicity of fields in which sustainability can and should be worked on, its concept and dimensions are not yet a consensus in the literature, assuming a polysemy and multi-disciplinary sense applicable to different situations, contexts, and objectives. Approaches varies according to different areas of knowledge and often within the same area. Likewise, Sustainability and Sustainable Development (SD) are approached as common concepts, albeit with differences between them.

Since the sixties, Sustainability has been aimed into the direction of development when, in the Brundtland Report [13], the concept of SD was proposed. This concept evolved, not only to harmonize but to integrate development with the environment when the concepts of Sustainability and SD emerged to translate this integration. Thus, from the 1980s, the term SD was assumed, whose concept was widely diffused assuming this as a form of development that seeks to meet the needs of the present without compromising the ability of future generations to attend to theirs as well.

It should also be noted that although the perception of the need to remain within limits of recovery has begun in the nature dimension, it is necessary to broaden the spectrum of what needs to be maintained, which must not be destroyed, as by cultural diversity. The idea of sustainability, then, it is not restricted to the beings of nature, it also involves other dimensions [14]. From the first five Pappas [1] dimensions: Social-cultural, Economic-financial, Environmental or Ecological, Technical or Technological, and Individual; three more were added by different authors: Relational or Convivial, Territorial or Geographical and Epistemological [15].

To introduce this model of development in the society, UNESCO [4] proposed that sustainability should be integrated at different levels of education, calling it ESD. According to UNESCO [4], ESD empowers learners to take informed decisions and responsible actions for environmental integrity, economic viability, and a just society, for present and future generations, while respecting cultural diversity. It is about lifelong learning and is an integral part of quality education. ESD is holistic and transformational education which addresses learning content and outcomes, pedagogy and the learning environment. It achieves its purpose by transforming society.

The ESD must be integrated into the learning content by integrating critical issues, such as climate change, biodiversity, disaster risk reduction (DRR), and sustainable consumption and production (SCP), into the curriculum. Also, ESD should be integrated in the pedagogy and learning environments by designing teaching and learning in an interactive, learner-centred way that enables exploratory, action-oriented and transformative learning and by rethinking learning environments – physical as well as virtual and online – to inspire learners to act for sustainability.

Additionally, should be integrated in societal transformation by empowering learners of any age, in any education setting, to transform themselves and the society they live in order to: 1) Enabling a transition to greener economies and societies (equipping learners with skills for 'green jobs' and motivating people to adopt sustainable lifestyles); 2) Empowering people to be 'global citizens' who engage and assume active roles, both locally and globally, to face and to resolve global challenges and ultimately to become proactive contributors to creating a more just, peaceful, tolerant, inclusive, secure and sustainable world.

The integration of sustainability into higher education, according to Wals [16], could follow two approaches: "bolt-on": adding new courses and modules that have elements of ESD; 2) "built-in": integrating sustainability in existing studies and research programs as well as in staff development. Resembling these, Rusinko [17] previously proposed four forms of integration that vary, depending on the combination of two variables: the maintenance of the general structures of the degree (or creating a new structure) for the implementation of sustainable aspects and the focus given to sustainability (specific for each discipline or more cross-cutting and interdisciplinary).

In addition, and related with the responsibility to implement ESD, this could be a process: 1) top-down process, posing it at the institutional level and transmitting it to schools, departments, degrees, and faculty; and/or 2) bottom-up, from active faculty but with definitive need of institutional support [8]. Other studies about how to introduce sustainability in curricula could be seen, namely, in Hansen et al. [18], Allen et al. [19], Dewulf et al. [20], Holgaard et al. [21] and Colombo et al. [22].

Working sustainability as specific disciplines is of fundamental importance, by one hand, because as Dewulf et al. [20] said when it is only transversal can have negative points such as, the fact of being worked by a non-specialist teacher in the area the subject becomes fragmented in other disciplines and, thus, there are overlap or aspects not covered, and to integrate it into another discipline does not have a logical sequence.

On the other hand, the lack of a transversal approach in all disciplines can put the theme as disconnected from the rest and thus the perception of its importance is diminished. Therefore, the teaching-learning methodology adopted is fundamental to minimize these negative points. For instance, project-based teaching, still with different denominations as Fourez [23] did when he proposed his "Island of Rationality" method to the diffused Project Based Learning [24,25], has already been highlighted as the most appropriate method for the construction of rooted sustainability knowledge for the training of future professionals.

This methodology is adequate for the interdisciplinary structure of education, in which there is the interaction of all agents of education. At the same time, the work is more interdisciplinary, promoting the interaction and integration of knowledge both for students and educators, thus favoring that Sustainability is placed at the same level as the other themes addressed in the different disciplines. Some examples have been exposed that evidence this [18,26–30]. The promotion of true learning about sustainability firstly involves developing in individuals the understanding and appropriation of the values of individual sustainability and the ability to change oneself intentionally. Thus, teaching-learning approaches should enable this objective of individual transformation to be achieved so that collective transformation is possible in the search for a sustainable society.

2. RESEARCH METHODOLOGY

In this paper, the authors intend to discuss the introduction of Sustainability in EE curricula, based on their active participation in a debate session of an EE conference organized in 2016. In the context of the conference, four authors of submitted and approved papers were invited by conference organizers to participate in this specific session. These papers had in common case studies and studies of sustainability integration in engineering degrees and programs from different countries: Spain, Portugal, Canada, and Brazil.

From the debate discussion, moderated by one of this paper authors, and from the session results that joined so many different ideas and perspectives, a question comes to authors´ mind:

- Is the introduction of Sustainability in Engineering Education curricula an achievable outcome or a utopia?

To contribute to the answer to this question, the authors presents this paper findings that are, mainly, based on the papers and presentations exploration of different approaches and strategies towards EESD in similar degrees but totally different contexts (North America, South America, and Europe). Also, results of teams discussion formed during this session are presented. Among the participants of the session were some first-year students of engineering.

3. STUDY CONTEXT

This section presents the study context where this study was based that resulted, mainly, from a debate session related with Sustainability. The debate session objective and organization as also the driving questions raised in the debate are exposed.

3.1. Debate session objective and organization

Beyond the regular paper sessions, the referred conference included debate sessions to stimulate the conference participants' discussion. A total of 16 participants (among authors' papers invited, regular participants and students) attended this session. The moderator/facilitator organized three teams with five, six and four members (*Fig. 1*). At least, one author 'paper was on each team, as well, a student.

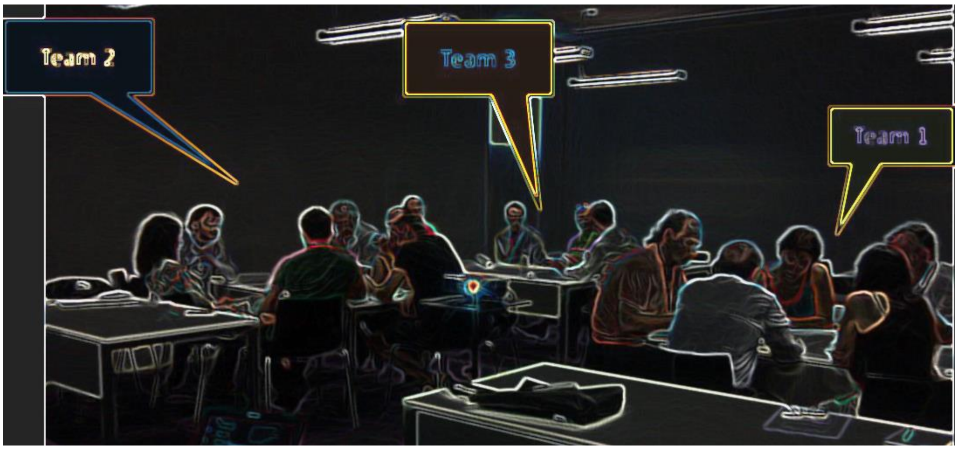

Fig. 1. Teams working (picture intentionally blurred for privacy purposes)

The debate session was organized in three main parts:

1) Contributors of each case study presented their findings and approaches in five minutes or less. Also, they launched one or two driving questions for the debate, according to findings from his/her paper. Main questions were registered and prioritized by consensus for the next phase.

2) Driving questions were registered after each presentation on the whiteboard, to facilitate the discussion phase and debate was started. A summary of consensus or disagreements reached was done for each team.

3) A short sum-up of main conclusions and ideas was developed altogether. It was tried to reach some answers (or new deeper questions) from the initial driving questions.

3.2. Driving questions for the discussion

In order to proceed with the debate (second part of the session), just eight driving questions, from 12 given by the authors invited were selected by consensus:

1. For an engineering education eminence level, which performance measures (in terms of efficiency, efficacy, effectiveness) could be used to evaluate sustainability competencies?
2. In addition to sustainability, should be used other drivers?
3. Sustainability approach: top down & bottom-up approaches - which should be first?
4. How to convince all instructors to include sustainability concepts in their courses?
5. How to ensure a proper scaffolding of the sustainability concepts from year to year?
6. Is there any consensus of what is a sustainable university? Is a comparison needed between universities? Or is it enough a self-comparison?
7. A great number of sustainability curriculum implementations and approaches but, how are students going to learn sustainability if the university is not sustainable?
8. Great efforts for cooperation for development in other countries, but what about solving real local problems?

Each team discussed a different group of questions, using a flip chart to collect the main ideas. Then, they were presented to all participants to be discussed.

4. RESULTS AND DISCUSSION

This section introduces the main key ideas from the papers and presentations as also the debate findings from each team.

4.1. EESD cases and studies key ideas

Each author had different objectives with the papers they submitted to the conference as can be seen in Table 1.

Table 1. Key ideas from papers and presentations

Countries	Key ideas
Brazil	Innovative experiences and proposals in EE for sustainability applied in a case of a Production Engineering program of a Brazilian university anchored on small projects (8) during the whole program.
Canada	Framework for implementing a sustainability curriculum in an Engineering Technology program. This framework should be implemented through a top-down and a bottom-up approach.
Portugal	Study of integration of sustainability in the engineering programs and courses of a Portuguese university through information contents in the university website. The authors revealed that very few programs and courses integrate sustainability.
Spain	Study of the contributions of different universities approaches to sustainability and social responsibility reports. This contribution was measured by sustainability assessment tools.

In the case of Brazil and Canada, the authors presented case studies of how they integrated or planned to integrated sustainability in specific engineering programs. Specifically, in the Brazil case, they considered that through projects, students could measure the sustainability performance by measuring the efficiency, efficacy, effectiveness and eminence level of these projects [31]. In the case of Canada, the authors also presented a framework to be used to integrate sustainability concepts into several courses of an Engineering Technology program [32]. They called this "Timeless Engineer Framework" where they defined "timeless engineer" as someone who is able to adjust to the needs of the world's dynamic challenges in order to create solutions that are consistent with the needs of current and future generations. This framework was not implemented at the time the author presented the paper.

In the cases of Portugal and Spain, the authors presented a more general view about sustainability. The authors from Portugal present the sustainability in engineering programs in their institution [10,33] and conclude that just a small percentage considered sustainability theme in their contents, in spite of sustainability initiatives in the university such as sustainability report, sustainability research centers, among others. The authors from Spain[34] presented a study developed by a sustainable engineering research team at Spanish university based on different university approaches to sustainability and university social responsibility reports. Their main objective was to better understand how to advance and measure sustainability in a university and the important role that students may play. They highlighted the important role of PBL as learning-by-doing methodology capable of enabling students understanding the SD.

4.2. Results of teams discussion

The results of the discussion of the teams were presented to the other participants in flip charts. These results were explained by each team at the moment they presented the flip chart to the others participants.

Team 1 answered to the questions 1 and 2 (section 3.2). Their filled flip chart exposed a need to have answers based on real facts (a real problem) to convince teachers and students in a reciprocal way to distinguish sustainable from what was not sustainable. Also, they considered a need of a system approach through a formation of a task force of consultants involving rectors, deans, teachers and students to produce a document with sustainability types and to evaluate them. Also, their opinion about how to teach were that students must teach students and sustainability evaluation must be mandatory. In order to achieve this, teachers must be trained in sustainability competencies and should be motivated to learn such competencies. In order to achieve this, teachers must be trained in sustainability competencies and should be motivated to learn such competencies (considered a driver).

Team 2 answered to questions 6, 7 and 8 (section 3.2). They showed two perspectives: 1) students are not able to be sustainable professionals if their academic environment is not. According to this team, it is necessary to instill sustainability mind-set; 2) joining forces of students' initiatives (developed in-class) and governmental support.

Team 3 discussed questions 3, 4 and 5 (section 3.2) and their opinion on these was that sustainability definition could have many meanings for different people. Nevertheless, ethical aspects, change minds and attitude should be present in all people to see sustainability in all dimensions, as referred in the literature review (section 2). Also, they considered that a bottom-up approach is better, starting with small projects and scaling up. Of course, this idea of bottom-up was not shared by all participants that considered both approaches are necessary, as also referred in the literature section.

To conclude this part, answers to the questions were marginally achieved what reinforces the difficulty to have direct responses to the questions formulated. But, at one point, they seemed to agree: all stakeholders (students, teachers, rectors, deans, society) must be involved in the on-going discussions and a mindset shift is needed because there are many universities where this did not yet happen. Involving all and with the proper mindset, sustainability integration in EE could be an achievable outcome. Right now, is still more a utopia than reality, but it was possible to see through some examples (e.g. case from Brazil) this can rather be achieved and come reality. It also seems consensual that the learning methodologies to concretize this achievement are learning-by-doing approaches or active learning. These methodologies seem a more suitable approach because involves the students in their own learning.

A lot of questions and challenges, also raised in the debate and that remained without an answer were: What should be the contents of courses/programs and how they should be related to integrating sustainability issues in a natural way? How to put the sustainability in the learning outcomes? What learning methodologies/tools to use in Higher Education Institutions in order to effectively change students' roles from spectators to sustainability key actors and change agents? The session revealed to be a short time-frame to discuss so many important topics related with sustainability.

5. CONCLUSIONS

This paper intended to give a contribution to the debate about introducing Sustainability in the EE curricula. The authors identified two case studies and two more general studies presented in an EE conference organized in 2016. The case studies focused on specific programs of specific universities of Brazil and Canada and the studies were developed in Portugal and Spain. The case study from Brazil is successful implemented, while Canada case was not and his author was afraid of the difficulties they will face (e.g. teachers' resistance). The other two studies showed that there is an effort to integrate sustainability in EE but more is needed. Though the different context and country, it seems concerns are the same: EESD and how it has been implemented and could be implemented. Also, how this should be achieved to form "timeless engineers" that attend sustainability issues in their professional practice. Active learning methodologies, and, in particular, PBL seems to provide a good solution defended by many authors, including the ones involved in this study.

It was also clear that the sustainability integration in curricula implies a mindset that is not yet achieved in all, and needs to be worked out, because, as stated earlier, true learning about sustainability involves, firstly, developing in individuals the understanding and appropriation of the values of individual sustainability and the ability to change oneself intentionally. As Colombo [14] said, based on Morin [35] this change needs to start at one point, and it seems that the best is with teachers, through training in the subject, which is corroborated by many authors. However, continues without being addressed. This was also one of the questions raised by the participants in the debate: Should we teach teachers to teach sustainability? The answer is yes, because, after all, teachers are more near to the students and act more directly in teaching, research, extension, but, mainly, in the construction/reconstruction of the curricular structures. Also, teachers have a role both in the top-down and bottom-up processes of integrating sustainability. These processes, which, as shown by several authors, including those analyzed here, must be worked on two lines. It must be a movement from the base, but also must be supported and institutionalized by the dome.

ABSTRACT

The Circular Economy Design Forum (CEDF) is an EIT RawMaterials educational project aimed at incorporating an entrepreneurial mind-set into engineering education, particularly in topics related to circular economy (CE). As part of this initiative, a new course was developed as a platform to promote a dialog between students, industry and academia. To use this educational platform effectively, a "Training the trainers" event was organized where teaching staff learned how to integrate an entrepreneurial mind-set into courses with technical content and how to support student innovation capabilities. In this paper, the objective is to explore the impact on the mind-set and motivation of students when: i) a circular thinking is promoted though iterative project work within the circular economy context, and ii) a customer-centric approach is incorporated in an engineering course, by letting the students identify real industrial needs together with stakeholders. According to the student's feedback, most of the participants (15/18) felt that the course supported well their learning on CE topics and enhanced their study motivation. However, it was also evident that additional support is needed for timid students that have trouble contacting stakeholders directly.

Conference Key Areas: Sustainability and Engineering Education, Curriculum Development, Skills and Engineering Education

Keywords: Circular Economy, Entrepreneurial Mindset, Project work, Industrial Collaboration

INTRODUCTION

The European Institute of Innovation and Technology (EIT) is a European initiative supporting innovators and entrepreneurs in the creation of solutions to tackle some of the most pressing societal challenges. One of such topics requiring attention is the increasing demand for raw materials, resulting of the continuous growth in world population and the demand of manufactured products per capita. The EIT RawMaterials Knowledge Innovation Community (KIC) was created with that aim, also supporting educational programs. In addition, the EU framework for education and training 2020 (ET2020) points strengthening entrepreneurship competencies as a strategic objective, and promotion of excellence in teaching as well as sustainable investment in education as priority areas [1]. Education has an important role in improving the entrepreneurship competencies and mind-set, especially for young people [2].

“Circular Economy” (CE) is one of the concepts that has drawn most attention in the area of raw materials production in recent years. CE aims at alleviating the need for primary raw materials in a sustainable manner by maintaining the intrinsic value of raw materials through efficient recycling practices. However, to understand and apply the main concepts of CE in industry, multidisciplinary ideas are required. As value generation lies at the core of the CE concept, an entrepreneurial mind-set of the actors involved in the materials production cycle is required. This need led to the “Circular Economy Design Forum” (CEDF), an educational project funded by EIT RawMaterials.

The CEDF offers an innovative approach as it started with the premise that the teaching staff in engineering education programs are not typically familiar with the basic aspects of entrepreneurship. Thus, this project offered a training session for teaching staff (in December 2016) and produced an entrepreneurial education “toolbox” to support the course development. In this event, staff members were introduced to customer-based thinking and other relevant entrepreneurship concepts.

In engineering education, problem-based learning [3] with the use of project work is a popular approach that is believed to promote the creativity of students [4]. However, in most cases, the students are typically assigned a pre-defined problem to be solved applying the main concepts of the course. In this kind of approach, it is not uncommon that the students start looking for an answer based on what they think will satisfy the teacher, thus limiting the development of creative learning. Furthermore, in real engineering work life, the search for solutions for pre-defined problems is seldom the case.

In contrast to the typical “linear” problem solving education, we aimed at implementing the CE philosophy in education and think rather circularly. For the student project work, this can be implemented in a form where the students discover a problem by themselves. To find a real working case, the students are forced to reach out to clients and stakeholders, making this a customer-centric approach to learning. Once the problem is identified, a potential solution can be proposed, but then, together with a mentor, the problem-solution pair needs to be evaluated and redefined iteratively, to find both a better problem definition and an attractive solution.

After various cycles – the most relevant problem can be discovered. This iterative process thus becomes a tool to foster innovation.

An entrepreneurial mind-set is not only valid for the creation of new ventures and start-ups but should be considered a general skill [2]. One crucial difference from learning based on pre-defined problem solving, is that entrepreneurs actively work to identify the problems that need solving in the first place. Thus, this skill is important for all engineers, whether they work in their own company or as employees [5,6]. An entrepreneurial mind-set can be learned via real development projects that are initiated by an active discussion with stakeholders to understand their needs [7]. Evidently, for this process, the students need careful advice and instructions on how to proceed, as it might feel scary and therefore, the students need constant checkpoints and transparent feedback of the evaluation process [8] to find the right motivation. The teacher may not be in charge on the project, but is still very much so in the educational process.

1 DEVELOPMENT OF THE CIRCULAR ECONOMY DESIGN FORUM

Effective implementation of an entrepreneurial mind-set into engineering teaching cannot be obtained by adding a few dedicated contact sessions in a course, but rather as a mind-set involving teaching style and assignments. The objective of this paper is to study how to implement these concepts to an engineering course having technical content, namely, the understanding of CE in raw materials processing. To ensure this integration, prior to the planning of the CEDF course content, a training event for teaching staff was organised to share good practices in the development of course structures involving entrepreneurship.

1.1 Training the trainers event

As mentioned in the Introduction section, the CEDF project was used as a training platform on which the teaching staff from various universities could learn from experience to work within an entrepreneurial framework. The staff worked in teams to learn how innovation-driven projects can be directed and how to provide effective feedback. The learning outcomes for this event:

- Help teachers add hands-on, entrepreneurial elements to their teaching
- (Re)design a course from the teacher’s local university to include elements of entrepreneurship in an interactive and hypothesis based approach

The event took place on December 2016, and was hosted by Aalto Ventures Program (AVP), a program within Aalto University with a strong history on the teaching of entrepreneurial skills at various levels of higher education. Nonetheless, AVP had no previous history on training educators in such a systematic way, upon which future training workshops can be provided. The timetable of the event and the themes discussed in the workshops can be seen in Table 1.

Table 1. Workshop topics for the CEDF "Training the Trainers" event.

Day 1	Day 2	Day 3
Intro to the workshop Pre-work video session	Lecture: Circular Economy by Markus Reuter	Teaching event with local students
Morning WS: "Student assigments and uncertainty"	Morning WS: "Feedback and teacher presence"	Student presentions
Afternoon WS: "Class culture + learning process"	Afternoon WS: "Learning objectives + grading + work load"	Feedback and discussion of the event
Own Course development	Own Course development	-

For the first two days the teachers were divided into teams that used one of the courses identified during the preliminary tasks as working examples. At the beginning of each workshop, the experiences obtained during a similar integration of entrepreneurial mind-set to a pilot Capstone course named Materials Processes and Synthesis (MPS, held Fall 2016), were introduced and reflected upon. Afterwards, the topic of the workshop was processed in the context of the developed courses in a team. Feedback on the content development but also on the team performance was provided to give the teachers an impression on how it feels to receive feedback. Thus, it became clear that constructive feedback for the students is important, since a negative or extremely critical environment does not encourage innovation.

During the last training day, a group of volunteer students from the MPS course (i.e., who had already experienced an entrepreneurial mind-set teaching) was invited to work on a case study. The task for the students was to develop a Stakeholders Analysis for sustainable business ideas and they were guided by the trained staff. Various iterations were carried out based on the feedback provided by the trainers. On the closing sessions, both the students and the staff members received feedback from each other and from the facilitators on their performance (*Fig. 1*). Since engineering teachers and professors tend to work with projects where is only a "one way to the solution", it was pointed out that the trainers tend to direct the students to the path they had considered appropriate. It is important to be able to guide the students at the direction they had decided and only set proper frameworks to encourage the students to identify their own path, however difficult that might be.

Teachers liked:
"Feedback provided new way of thinking and tools"
"Being as a student"
"The active way of teaching"
"Good experience the student group mentoring"
"The way of how the class were performed"
"I also liked the teachers giving creative feedbacks"

Fig. 1. Feedback session with the students and teachers [Photo by R. Serna] as well as written feedback provided by the participants.

1.2 Selected teaching methods and their alignment

With the aim of creating a "forum" as its name suggests, the overall approach for the CEDF course was that, instead of the classical "lecture + exercise" model, a dialogue-based education was promoted. We invited experts on the field of CE from different organizations willing to engage the students into considering the CE concept from different angles. To promote the discussion of the various aspects of CE and promoting a dialogue with industry, the teaching and assessment methods were carefully selected to support the intended learning outcomes (ILO). The ILOs presented in *Table 2* are aligned with the teaching methods and assessments as suggested by Biggs and Tangs [9].

Table 2. The ILOs aligned with the teaching method and assessments.

ILOs	Teaching method	Assessment
The student has learned the main concepts of CE and their relevance in the production and processing of metallic raw materials	Workshops (Introduction, Re-Think, Sitra), group discussion, Excursion	Circular Economy Essay 1 and 2, Project work
Developed entrepreneurial thinking from a CE perspective	Workshops (Re-Start and introduction) Group discussion	Circular Economy Essay 2, Project work
Modeled innovative recycling processes to determine their feasibility and environmental impact	HSC training, Re-Act workshop	Disassemble report (Re-ACT)
Applied their knowledge to solve project relevant for industry, including aspects of economic analysis	Re-Act workshop, Project work	Project work
Worked in a multicultural team	Project work	Project work

The largest individual assessment method was the 2 CE Essays where the first was written at the beginning of the course to determine their initial level of understanding of CE, and the relevance of entrepreneurship and value creation on it. The second essay was prepared at the end of the course as a reflection to learning. Both Essays included a graphical representation of CE. The assumption in this study was that the depth of the CE concepts in the second essay should reflect the efforts that each student had invested to the course. In total, the essays formed 25 % of the total grade and the rest 25 % by other individual tasks. Additional activities to support the lectures included a hands-on workshop on WEEE dismantling and an excursion to an industrial recycling facility.

Thus, the group project work used to evaluate how the students apply the concepts of CE provided the rest 50 % of the grade. The aim of this study was to discover if the students could generate a dialogue to industry and identify issues on CE that address industrial needs and have the potential to create some added value. Another hypothesis in this work was that when the students are required to identify a stakeholder company and a topic by themselves, they will feel more engaged. This also puts in practice the idea that with an entrepreneurial mind-set, relevant problems are discovered through dialogue with clients [7]. Four feedback sessions were set between teacher and the student groups to assess the problem-solution pair in an iterative manner.

2 LESSONS LEARNED FROM THE CEDF COURSE

In Spring 2017, a pilot CEDF course was held with the participation of 18 students: 15 from Master's and 3 from Doctoral level. The participants were students from different disciplines, including process engineering, materials science, chemistry, mechanical engineering, physics, business and arts. In addition, the students formed a multicultural group, having representatives from various nationalities.

As the CEDF course was quite short (5 ECTS) it was necessary to maximize the active learning process during the contact sessions and minimize information sharing by lecturing. A detailed schedule of the course is presented in *Fig. 2*. The black text indicates the topics of workshops, while the blue text shows the project work milestones. There was also relevant literature provided to the students that they could select according to their specific interests and use as reference a material in the essays. By week 2, an industrial process simulation software (HSC SIM 9, Outotec) was introduced as a tool that could be utilized in the project work to assess the resource efficiency and footprint of selected technological business opportunities [10]. This was utilized by 3 out of the 5 groups in their project work.

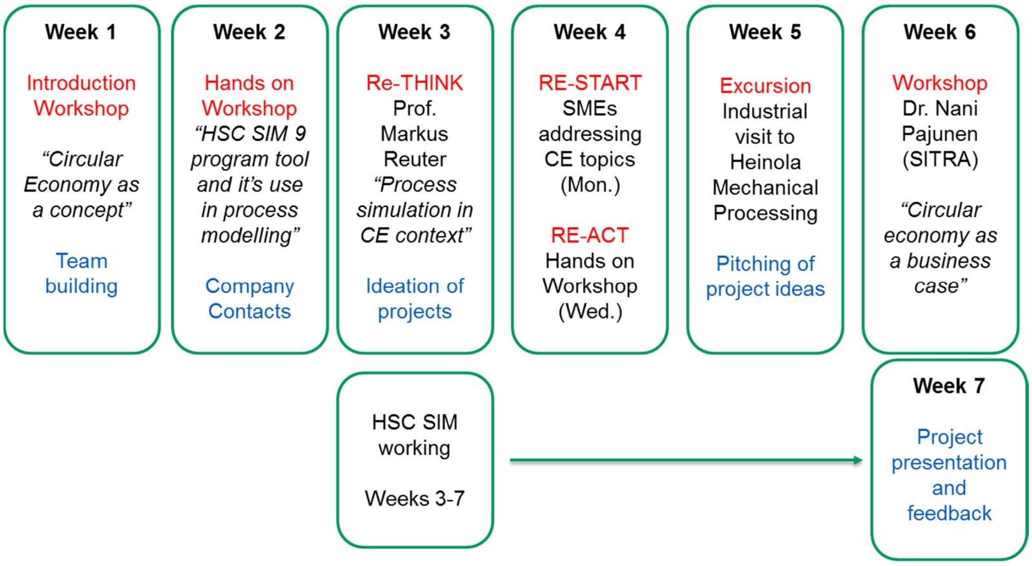

Fig. 2. CEDF structure: black text describes the events and blue project milestones.

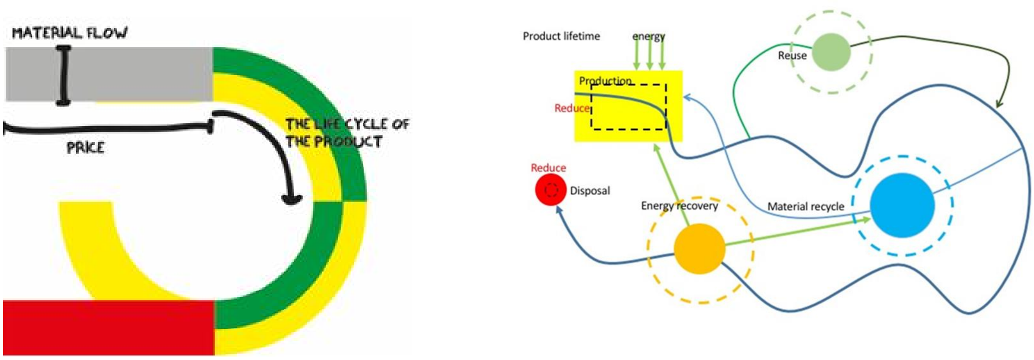
For the personal assessment, students prepared two essays to show if the CE concepts had been strengthened during the course. These essays also involved visualization as exemplified in in *Fig. 3*, where it can be clearly seen that at the beginning of the course, most of the students had implemented just linear or basic round visualization for CE.



Before CEDF After CEDF

Fig. 3. Example of a student's visualization of the CE before and after the course.

In comparison, after the course, all the students had implemented a round visualization but with iterative nature. In most of the second visualizations, scenarios that are more complex were presented: waste creation at different stages, additional energy input, social and economic aspects. New ways to utilize end-of-life products were taken into consideration and the possibilities for new business models like leasing or renting were considered. Especially with the students that participated in most of the workshops, numerous references were included in the essays and the conceptual understanding of CE was deep. It is worth mentioning that at no point was any memorization encouraged (essays were prepared from home).

Each team selected a company that they interviewed on their ideas and needs on CE solutions. The selected companies represented wider range of industry than if selected merely by the teaching staff: from metal industry to real estate business. As was aimed in the study, all groups were able to identify interesting development targets by the interviews; however, all topics were scoped during the mentoring sessions. In the end, the projects proposed different improvements to CE practices in the selected companies, for instance by utilization of side or waste streams, improving logistics efficiency or new business models (leasing).

From the student feedback, it was observed that most of the students (15 out of 18) stated that the teaching methods supported their learning and their study motivation had improved slightly or notably during the course. The students also pointed out that they felt very engaged in the project because they felt excitement about developing a project with a typical entrepreneurial approach. In addition, they considered that the course content was very relevant for their future career and they enjoyed working at the interface with industry. Admittedly, some students expressed that this approach felt intimidating and is more demanding than their typical Master's degree courses.

3 CONCLUSIONS AND FUTURE WORK

The aim of this project was to incorporate an entrepreneurial mind-set to engineering courses having technical content, and to discover if this approach supports the development of circular thinking required in CE. In the first approach the participants prepared project works where they interviewed stakeholders and identified problems. All groups found projects that were very innovative and provided interesting CE solutions, thus some groups needed additional mentoring to narrow down their topic. According to the student feedback, most of the participants felt more engaged in these projects than with regular pre-defined projects and reported that this course clearly enhanced their study motivation. In the second approach, reading material and workshops with stakeholders were provided to enhance the learning of concepts on CE and this clearly influenced on the students thinking, as reflected by the second essays and especially in their more intricate visualisations.

For the teaching staff, one key finding during the course is how multidisciplinary the CE concepts are. If real innovation on this area is needed, multidisciplinary teams are required to provide solutions from engineering, business and design perspectives. In the future, the forum may be developed towards a platform where different stakeholders meet and discuss the challenges of CE. As additional material, videos created as part of the CEDF project describing the experience of introducing entrepreneurial aspects in engineering teaching are available in the following links:

Ideas before the course: https://www.youtube.com/watch?v=BsILM0n2wG4

Ideas after the course: https://www.youtube.com/watch?v=s3JjNLAVRps

4 ACKNOWLEDGMENTS

The Circular Economy Design Forum (CEDF) is an educational project funded by EIT RawMaterials. We thank Aalto Ventures Program (AVP) for their mentoring during the course preparation and the facilitation of the "Training the Trainers" event.

ABSTRACT

Projected urban growth in Kenya will require increased engineering talent and resources to facilitate the infrastructure demands of growing urban centers [1]. This study aims to understand how Kenyan institutions are currently equipped to support engineering programs and what factors need to be considered to reform the curricula to support rapid urban growth in the region. To investigate these questions, a research team travelled to Kenya in July, 2016 to study the engineering programs and interview faculty members at two universities. The method of currere was used as a framework for analyzing the regressive, the progressive, the analytical and the synthetical. Four key insights emerged from the study: opportunities exist for curriculum reform of Kenyan engineering curricula to mirror emerging engineering pedagogy and practice, context is a critical factor in curriculum reform, accreditation is a key consideration for online learning in engineering education, and there was an openness to collaboration regarding curriculum reform. This study focused on the perspective of the educational institution. As such, further research is suggested regarding the institutional factors, notably the accreditation standards for online learning, the industry objectives and the policy objectives to inform the context of the conversations of engineering education in Kenya.

Conference Key Areas: Sustainability and Engineering Education, Open and Online Engineering Education, Curriculum Development

Keywords: Engineering Education, Online Learning, Curriculum Reform, Accreditation

[1]A. Despres-Bedward
Antoine.Despres.Bedward@mail.utoronto.ca

INTRODUCTION

Kenya is experiencing significant urban population growth [2]. In order to accommodate this growth, there is a substantial need for additional engineering talent and resources to design, build and manage new and sustainable city infrastructure. A large component of this capacity building will be achieved through the education and training of engineers who can use sustainable approaches to build and maintain new infrastructure [1].

Researchers from the University of Toronto recently met with faculty members in engineering at two large public universities in Kenya. Their visit was part of a larger project that is exploring a curriculum for engineering education for sustainable cities in Africa. The goals of this particular study were to build on the literature surrounding engineering education in Kenya, discover how the country is prepared to manage current and future urban growth rates through engineering education, and explore the potential of developing an online engineering education curriculum that is accessible and locally contextualized to promote the sustainable development of growing urban centers. The findings from the study will set the stage for deeper study in to the larger research.

The method of currere [3] was used to explore the conversations regarding engineering curricula, those involved in the conversations and the surrounding contexts in Kenya. The method of currere encourages researchers to analyze their own experiences in relation to the cultural, historical and political contexts of education to understand more fully, with more complexity and subtlety, the current realities [4]. This is accomplished through consideration of the regressive, the progressive, the analytical and the synthetical aspects [3].

Both researchers felt it was important to discuss the intent of the project due to the prospect of interfering as opposed to supporting, as other prior interventions were criticized of being neoliberal in nature. Extensive and proper consideration was taken when framing the following research questions:

1. How are institutions currently equipped to support engineering education in Kenya?
2. What factors need to be considered to reform the engineering curricula to support rapid urban growth in Kenya?
3. What lessons can we learn from conversations with universities in Kenya?

1 LITERATURE REVIEW

Engineering education was introduced in Eastern Africa in 1956 as part of the University of East Africa, which separated into three distinct universities in 1970: one in Kenya, Tanzania and Uganda. The presence of accredited engineering programs has since expanded to nine universities in Kenya recognized under the Engineers Board of Kenya (EBK) accreditation body.

Amutabi (2003) and Case et. al (2016) note that politics play an important role in the development of society as they impact the structures of modern societies [5], [6]. Gaining its independence from England in 1963, the political climate in Kenya had a significant impact on the development of the country's education system [6]. The country experienced a period of politically motivated, rapid expansion in universities during the 1980s [5]. Universities were overloaded as their infrastructures and resources were not equipped to handle such a large number of students. This was especially challenging for engineering programs which require a balance of theoretical, practical and experiential learning [7], often requiring many resources outside of the classroom, including laboratory space and equipment, in addition to the human capacity required to facilitate this learning.

The emphasis on financial investment in tertiary education was later diverted to elementary and secondary education [6]. As a result, universities removed tutorial sessions - an important part of engineering education - to deal with the problem of underfunded and understaffed faculty. Tutorial sessions provided opportunities for students to participate in discussion: an important part of student curricula due to the importance of reflection in learning [8].

Acknowledging the historical context that shaped the engineering programs in Kenya, this research study aimed to understand the current state of the engineering programs, how they were influenced by this historical context and how the engineering curricula may reform in the wake of engineering education research and evolving societal needs.

Curriculum reform is a popular topic in engineering education literature as engineering education and the training of engineers are considered key to the progression of the economy [6]. Kenya's rapid urban growth brings to light two pressing questions regarding curriculum reform: how can the engineering curriculum evolve to incorporate emerging knowledge regarding sustainable urban development?; and, how can engineering curriculum be scaled to build the engineering capacity required to tackle the growing infrastructure demands expected to emerge as the cities continue to grow?

With the increase in popularity around online education, specifically in engineering related courses, there is a growing opportunity to share educational resources internationally and to seek ways in leveraging the benefits in a Kenyan context. Online learning is viewed as a way to increase access to education to students who cannot afford the cost of tuition, and decrease the commuting volume of students who are already registered.

As an attempt to capitalize on this potential, the World Bank introduced the African Virtual University (AVU) project in 1998 [9]. The goal of the project was to support what it viewed as failing higher education in Sub-Saharan Africa by introducing high quality education to Kenya through modern information technology systems. The hope was to educate individuals through distance education and increase the number of well-trained African scientists, technicians, engineers and business managers required for economic development [9]. However, the World Bank's association with the AVU project was viewed by some as a source of neoliberal policy models imposed on developing countries. Despite the intent of offering courses focused on engineering, a search for engineering courses on the AVU website yields no results.

The literature on engineering education in Kenya paints an incomplete picture of the country's ability to deliver to the discipline in an online setting. Studies of the status of engineering education in Kenya were few and far between. Based on their impressions and experiences in engineering and education research, the researchers felt that such little information available presented a need to study the institutions more closely and in person.

2 METHODS

This study into engineering education in Kenya used data collected from a larger project for the development of engineering education for sustainable cities in Africa. The project collected data from a variety of educational and cultural contexts that included engineering education at universities in Africa. Interview data relevant to the Kenyan context were selected from the larger project.

2.1 Participants

Ten faculty members from two public Kenyan universities were interviewed for this study. Participants were chosen based on their experience in engineering education and their availability during the visit. For each case, participants underwent a formal consent process prior to their involvement. This process followed the ethics procedures of the University of Toronto. The identities of both universities have been anonymized to KU1 and KU2 (i.e. Kenyan University 1 and Kenyan University 2). The identities of the participants have been anonymized to participant 1, 2, etc. Participants 1 to 4 were from KU1 and participants 5 to 8 were from KU2.

2.2 Data Collection

A semi-structured group interview was conducted at each university, recorded, and then transcribed. Interviews lasted 60 to 90 minutes. Interview questions were structured around seven themes: cities and urbanization, engineering education, online and distance learning, scalability, sustainability, virtual labs, and engineering employment. Group interviews were used to explore contemporary engineering-education contexts in East Africa, survey engineering-education approaches including online learning strategies and methods, and integrate knowledge gained to devise highly scalable engineering education approaches suitable to resource-constrained settings. All interviews were contextualized by individuals' learning and cultural contexts. Field notes were also taken as part of the data collection.

2.3 Data Analysis

Using the currere method [8], data from conversations related to engineering education were extracted from the interview transcripts. Both researchers analyzed both sets of the transcripts. They then reviewed and discussed relevant information. An inductive approach led to the extraction of relevant information and avoided the biasing of the results [10]. Selected information emerged from the phrases that revealed details related to devise highly scalable engineering education approaches suitable to resource-constrained settings. The identified details were then triangulated across locations and participant roles. The combination of the two data sources facilitated a deeper understanding of engineering education in Kenyan universities.

3 FINDINGS AND DISCUSSION

A strength of the method of currere originates from framing the curriculum as a conversation or a series of conversations [4]. The interview questions elicited several conversations surrounding the state of engineering education in Kenya. The content of the conversations varied from one university to another, however, the topics below were present in each interview.

3.1 Opportunity for Curriculum Reform

The opportunity for curriculum reform emerged throughout the interviews. Participants acknowledged that there is a need to revisit traditional approaches to engineering education from a pedagogical and content perspective to keep up to date with emerging technologies and advances in engineering pedagogy and practice.

It was noted that the undergraduate curriculum had not been extensively updated from the initial curriculum developed in the 1960's (KU1) which was created under British influence. Topics that have since gained attention, such as sustainability, have not been explicitly incorporated into the curricula. The universities "teach the hard engineering" (participant 1), focused on theory, and acknowledge that "the curriculum is long due for review" (participant 1). Faculty, however, did not see this as an independently driven initiative, suggesting that "[we] need the innovation, the outreach, [and] the new ideas from the developed world institutions… [such as] America, Britain, [and] Canada" (participant 2).

These institutions have content connected to emerging practice in engineering. However, the inclusion of these topics is generally limited to graduate degrees, such as programs dedicated to climate change and hydrology, and are not formally a part of the undergraduate curriculum. Informal inclusion of emerging topics in engineering in the undergraduate curriculum stem from individual instructors who choose to adapt their course curricula to include topics of interest (KU1).

In addition to the potential for updating content, participants discussed the opportunity for reform of the pedagogical approach to their engineering programs. In the current structure, the universities provide the theory in the classroom and the graduates need to gain exposure to the field outside of their studies. This may come in the form of practical attachments, where students have the opportunity to work in industry throughout or following their studies, or through other experiences sought after by the student (KU1 and KU2). The challenges with incorporating these practical experiences into the curriculum come from limited resources. As one participant stated, "it's difficult to [increase the practical component] in the university with the number [of students], with minimal finances [and] with minimal equipment" (participant 5).

Further, the demand for these programs, notably civil engineering, far exceeds the capacity of the program to accept the students, noted by one participant "we find that many students would like to come to civil engineering … but we don't have the capacity to absorb them all" (participant 3).

These issues produced conversations about the need for several changes including classroom setup, delivery method and curriculum design that may allow for a shift in the teaching approach and the increase in program capacity. Through these conversations, the opportunities for emerging technology in engineering education came to light allowing us to explore whether there are ways that online resources could be used to assist with the pedagogical shift facing the engineering programs and the apparent limited capacity for growth.

3.2 Importance of Context in Curriculum Reform

Context emerged as a key factor in the conversations regarding curriculum reform as it impacts both curriculum content and engineering pedagogy.

In the case of urban infrastructure, participants noted the disparity in urban development between developed and developing countries:

> In the context of our cities, I would say it is a little bit different than developed countries where the government puts infrastructure first and then people second. Here we settle first. Then people come ... then infrastructure comes. So, we develop from our village then to a town then to a city. And in that transition, the key challenges will be socio[technical]. (participant 3)

These types of localized differences with regards to urban development would lend themselves to different course content: different case studies, different approaches to design, or use of different technologies. As such, content developed for the Canadian context would not necessarily be relevant for the Kenyan context.

The political and institutional contexts were noted as a factor in curriculum reform with regards to pedagogy and content. Participant 4 described their lack of autonomy in curriculum development as follows:

> The main stumbling block has been the accreditation body. They tend to be quite traditional and, I think, in the future as those members are phased out, we will be able to offer some of this new program because some of these sustainable concepts, I think, they cannot wrap their minds around it.

This contradicted another participant who indicated that the "accreditation does not get involved in the material. They look at the curriculum and how we deliver. They really don't get involved" (participant 6).

This localized context can play a significant role in the development of curriculum, where one institution feels stifled by the accreditation body and another institution feels like they have autonomy in their curriculum development. In this case, one solution that may be appropriate for one institution may not be appropriate for the other. The accreditation factor is further explored in the subsequent section as it plays a role in the considerations for online learning.

These findings were consistent with a research study that focused on the significance of context for curriculum development in engineering education in Kenya, Tanzania and South Africa. This study highlighted the importance in considering context in curriculum design, finding that historical context, political objectives, industry objectives and institutional objectives influence curriculum reform through accreditation and funding, availability of resources, expectations of graduates and departmental autonomy [6]. Without an understanding and consideration of context, interventions are at risk of being less effective.

3.3 Accreditation Considerations for Online Learning

Accreditation emerged as another topic conversation in the design and development of online learning material. Differing opinions between universities arose during the conversations of online learning implementation. Participant 3 from KU1 stated:

> We cannot replace the existing [curriculum] because EBK has an issue especially for undergraduate. So, the only thing that can be done is, as he said, when we look at the soft or easy options [for online learning]. First engineers who are in the field we upgrade them to online. At the same time, there are those who want to do their masters where EBK does not play a role [in the curriculum]... But then later on when maybe EBK [becomes] a bit more understanding then [online learning] can be scaled down to bachelors.

This excerpt demonstrates barriers to the introduction of online learning in undergraduate engineering courses and suggests using online learning in graduate courses first. Participant 4 from KU1 further added to the accreditation barrier of implementing online engineering courses at the bachelor level.

> So, that has been a challenge in terms of incorporating teaching the open [online] learning. I think some courses can be replaced such that you have distance learners using technology, video conferencing satellite and so on. But

> these are concepts that the [EBK] currently, as constituted, cannot accept. So, as those members are phased out and we bring in you guys with fresh ideas, we will be able to catch up with the rest of the world.

A different response was provided regarding involvement of the accreditation body during our conversation with the participants form KU2. One of the researchers asked if the accreditation board limited what they could put online as far as course material. Participant 7 responded, “no.” Participant 6 added that “accreditation does not get involved in the material. They look at the curriculum and how we deliver. They really don't get involved.” The conversation progressed to a discussion around the implementation and evaluation of their online courses.

> We have caught areas where we are able to have parallel groups. Group going through conventional way purely another one going through blended mode purely, but they take the same examination and then you check: is this mechanism or the style of delivery mode capable of teaching? And we have proved that the distance education is capable of teaching just as well as the conventional teaching. So, the end product is one way of judging and so on. (participant 8)

These differing responses provide direction for further exploration into the standards for online learning set by the accrediting body, EBK. It is not clear why participants 6 and 7 responded to the question with optimistic certainty while participant 4 professed a lack of optimism and the presentation of a barrier by the same accrediting body. It was disclosed to us during our visit to Kenya that the accrediting board was made up of members primarily from a single university. If this is true, it may begin to explain a difference in comfort with new ways of teaching at the different institutions, and expand the scope of the research to include the role of the accreditation board.

3.4 Openness to Collaborate

Ensuring that the project team was pursuing the study ethically with the universities in Kenya was an important aspect stated at the beginning of the paper. The researchers did not want to be perceived as interfering in their affairs or imposing their own doctrine. Fortunately, participant feedback from both universities validated our inquiry into engineering education in Kenya. A sentiment shared by participant 8 when they expressed an openness and desire to collaborate:

> [We] are generally ready to collaborate in this process in seeing how it can translate into some tangible things later on when the research part of it is completed and recommendations and suggestions started.

This sentiment affirmed our belief in a beneficial outcome of our team’s presence in the region and undertaking of the study. A senior administrator also made an appearance while we were conducting our interviews. They expressed an interest in signing a memorandum of understanding for further collaboration between our universities on this matter. This confirmed an openness and desire for collaboration between the research team and both universities in Kenya.

4 CONCLUSION

Using the method of currere framed under the three research questions, four key insights emerged from this study:

1. Opportunities exist for curriculum reform of Kenyan engineering curricula to

mirror emerging engineering pedagogy and practice;

2. Context is a critical factor in curriculum reform, especially when considering inter-institutional or international collaboration of developing learning resources;
3. Accreditation is a key consideration for online learning in engineering education; and,
4. There exists an openness to collaboration regarding curriculum reform.

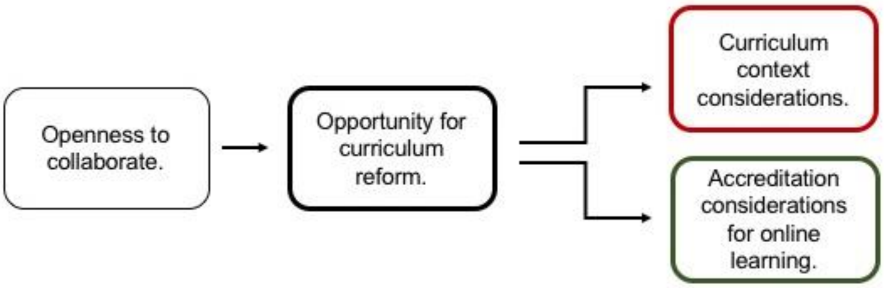

Fig 1. Progression of four key insights.

Although there is opportunity for reform, challenges for addressing the growing need for engineers in Kenya emerged throughout the research study. Limited institutional capacity, including physical, human and technological capacity, limited funding, and unclear curriculum accreditation standards all present challenges for the scalability of the engineering programs. These findings, coupled with an openness from both universities to collaborate, present an opportunity to explore online and distance learning initiatives that have the potential to address both pedagogical challenges, as well as curriculum content challenges.

The findings from this study may be used to inform design and collaboration considerations of the larger research project, or any other similar undertaking in the region. As context emerged as a critical factor in curriculum reform, more research is suggested regarding the institutional factors, notably the accreditation standards for online learning, the industry objectives and the policy objectives to inform the context of the conversations of engineering education in Kenya.

ABSTRACT

This cross-over study compares student laboratory work conducted in two different learning modes: first as a practical hands-on exercise and second using computer-based simulations. The research methodology was optimized to avoid other effects on the learning outcome. To evaluate the influence of the mode, short tests on knowledge gained during the previous experiment were conducted at the beginning of the next laboratory session. In 2016, forty students have taken part. Overall learning results of hands-on experiments were slightly better than those of simulated laboratories, but the difference in performance was not statistically significant. The study is continuing in 2017 with 30 participants. In addition to the knowledge tests, after each laboratory session the students were asked for their opinion in an online survey. A similar percentage of the students stated the execution of the experiments is beneficial for their future professional life. In the hands-on learning mode more students expressed they have acquired new knowledge. Although more students assessed the simulated laboratories as more challenging compared to hands-on experiments, more students mentioned obstacles while conducting the hands-on equivalents.

INTRODUCTION

It has been shown that hands-on student laboratory work can significantly influence the outcomes of student learning [1]. Nevertheless, many universities and vocational training institutions conduct laboratories as simulated experiments instead [2]. This is due to the costs of proper laboratory equipment to engage students in effective learning. Another reason is the increased amount of supervision to conduct hands-on labs safely, especially when the object of the experiment is potentially dangerous, such as lithium-ion battery cells [3].

1 RATIONALE

Numerous studies have presented mixed opinions on whether hands-on laboratory work is more conducive to learning than the simulated laboratory [4, 5, 6].

Reflecting on the results of such studies, Ma and Nickerson concluded that many studies did not allow the researchers to reach definite conclusions [2].

Making clear conclusion on learning effectiveness of different modes of laboratory exercises is hampered by design of the abovementioned studies. For example, students conduct hands-on experiments in groups whilst on campus, but are engaged in simulated exercises over the web and individually [6]. As the learning mode is mixed with other influences (in this case supervision, cooperative learning effects, distance learning, instructional papers, synchronicity, etc.), such research compares the combination of all aspects and is unable to specifically identify the difference in learning effectiveness of hands-on and simulated experiments.

The present study compares learning outcomes of student laboratory work conducted in two different modes: first as a practical hands-on exercise and second using computer-based simulations. In order to provide more reliable insights, this study optimized research methodology to avoid other effects on the learning outcome during laboratory work. The student experiments were strictly designed in such a way that the content and procedure were identical in each mode.

2 APPROACH

Each group was taught the same four content areas related to lithium-ion battery cells: two as practical hands-on experiments and two as computer-based simulations. The first group completed the even laboratory sessions as hands-on experiments and the odd ones as computer-based simulations. Planned as a cross-over study, the second group of students were taught the same topics by means of the opposite learning mode. To evaluate the influence of the mode on student learning, short tests on knowledge gained during the previous experiment were conducted at the beginning of the following laboratory session. The mean group results were compared, to answer the question: which mode has been more successful? Additionally, the students were asked for their opinions on each laboratory session in an online survey.

2.1 Learning objectives of the laboratory

Electrochemical cells are a wide and rapidly evolving field. It was therefore decided to limit the new laboratory to teach the most relevant transferable skills and knowledge that are beneficial for the students' future careers. First, they should strengthen their understanding of the characteristic behaviour of battery cells. Second, there is a focus on gaining practical knowledge of the most important parameters of cells and how to determine these parameters self-sufficiently by means of appropriate experimental setups. With these competencies students are enabled to design experiments with energy storage systems.

The identified learning objectives where grouped to four main content areas: (A) contact and isolation resistance, (B) open-circuit voltage, (C) internal resistance and power, and (D) energy of cells. Grouped in these areas, seven laboratory experiments were designed in such a way that they could be conducted in both modes in the same manner:

- Low Resistance Measurements (A1): Students discover that a multimeter is an inaccurate tool for low ohmic measurements, in the mΩ range, and why such measurement is a misuse of the multimeter. They learn how to use alternative procedures for low ohmic measurements, including a four-wire measurement in AC and DC.
- Contact Resistance (A2): Students conduct experiments with a variety of contact resistance values of typical electrical connections in battery systems.
- Isolation Resistance (A3): Students learn to estimate the influence of moisture on the isolation resistance.
- Open Circuit Voltage Curve (B): Students investigate the dependency of the open circuit voltage of a cell on the state of charge. They use two different types of lithium-ion cells.
- Internal Resistance (C1): Students learn to use AC- and DC- methods to measure internal resistances, being aware of the temperature dependency of battery cells. Students learn to approximate temperature changes caused by a power loss inside a cell.
- Power (C2): Students investigate the maximum discharge rate of battery cells. Students discover the dependency of maximum discharge power from state of charge, pulse duration, and temperature.
- Energy and Capacity (D): Students determine the capacity of a lithium-ion cell and learn about the factors influencing it. They learn to calculate the energy efficiency of both charge and discharge cycles.

Instructions affect the learning outcome of an experiment, e.g. the guidance level can strongly influence student exploration [7]. Thus, for each experiment only a single set of instructions was created and then used in both laboratory modes.

2.2 Creating two comparable groups for the cross-over study

Over the last two years, students enrolled in the energy storages course, were split into two comparable groups based on their prior practical experience to ensure a similar group environment for the individual students.

Forty students were enrolled in the laboratory subject in summer-semester 2016. Thirty students were enrolled in summer-semester 2017. The full semester group in the study program "Electrical Engineering and Electric Mobility" at Technische Hochshule Ingolstadt (THI) is participating in the mandatory laboratory. All students were asked to join the study.

To conduct this educational research as a cross-over study, it was essential to separate the enrolled students into two comparable groups. In this type of study, differences of the compared groups' average performances are detected and equalized by statistics. With the goal of isolating the learning mode in the experiment, we have to consider the in-group interaction in laboratories. Webb found that the same student may have different experiences in different groups, with consequent effects on his or her learning [8].

It was assumed that students with more practical experience may perform better in laboratories than their peers with a lesser practical background. Therefore, in order to assess the level of students' practical experience a preliminary questionnaire was developed. Each year, after analysis of the student responses, students were assigned to two laboratory groups to ensure a similar mix of students with practical experience in each group. [9]

Each student created a code-word that could be used to identify the same individual, while keeping all participants anonymous. Later two lists with code-words were publicized to inform the students which group they were assigned for the laboratory sessions.

2.3 Conducting laboratories in content areas A to D

Each group completed experiments in the four main content areas, two as practical hands-on experiments and two as computer-based simulations. The first group completed the even experiments as hands-on experiments and the odd ones as computer-based simulations. Planned as cross-over study, the second group of students were taught the same topics by means of the opposite learning mode.

For the content area A in simulation-mode, a newly created simulation-website was used. For areas B to D a black box simulation of the hands-on equipment [10] and the battery cell was used. To minimize influences from the user interface to control the experiments, the simulation was accessed through the same graphical user interface as the real hands-on devices. The simulation model emulates all observed effects of the real battery cell and the hands-on devices. The cell simulation model was parametrized to match the outcome of the hands-on experiments.

Each group was split into smaller learning groups of three to five students. The laboratory groups and the learning groups remained unchanged to limit any effects on the result caused by changing cooperative learning.

The students worked autonomously in a supervised environment. All groups were asked to prepare a written laboratory report for each content area before the following session.

2.4 Online survey after conducting the experiments

The students where asked for their thoughts on each laboratory session in a short and fully anonymous online survey. This survey is conducted in both laboratories of the department (chemistry and energy storages) to improve the laboratories. Adequate questions were evaluated to compare the learning modes:

(1) “By conducting the experiment I gained new insights today.” (Original: “Ich habe heute durch den Versuch neue Erkenntnisse gewonnen.“) This was a yes/no answer and coded 1 or 0.

(2) “At which point in the experiment did you have the biggest problem proceeding with the experiment?” (Original: „An welcher Stelle im Versuch hatten Sie am meisten Probleme voranzukommen?“) This was a free text question which was not compulsory. For data evaluation, the information was coded to 1 if any problem was mentioned or to 0 if students wrote nothing or were expressing they had no problems.

(3) “The procedure of the experiment is quite difficult (1) / feasible (0.5) / easy (0)” (Original: „Die Versuchsdurchführung ist recht schwer (1) / machbar (0.5) / leicht (0)“) The answers were coded in a three step Likert scale.

(4) “The content of the experiment is also relevant for me outside the university; I can imagine that it will be beneficial for my future professional life.” (Original: „Der Inhalt des Versuchs hat auch außerhalb der TH Relevanz für mich; ich kann mir vorstellen, im Berufsleben Gewinn aus dieser Versuchsdurchführung zu ziehen.“) The answers were coded in a five step Likert scale: fully agree (1) / somewhat agree (0.75) / maybe (0.50) / somewhat disagree (0.25) / disagree (0)

2.5 Testing the learning outcome

To evaluate the influence of the mode on the student learning, written tests on knowledge gained during the previous experiment were conducted at the beginning of the next laboratory session.

These tests lasted ten minutes and contained a mix of descriptive and multiple choice questions, free answers, and drawings. A positive point system (similar to tests for giving a mark) was used to evaluate the results.

The tests were conducted anonymously. Students were coded through the same self-created code-word used in the questionnaire for grouping.

A priority while planning both semesters was to keep time gaps between experiment and the corresponding test equal for both groups. For organizational reasons, this was not possible at the first content area A in 2016 [9]. In 2017 the laboratories are on the same weekday morning and afternoon, making it easier to keep the experiment – test time gaps equal for both groups.

For the tests, the goal was to always use the computer lab to provide the same environment sitting at a desk while completing the tests. The tests were evaluated and rated using a point system. The average group results between the hands-on and simulated modes were compared, to answer the question: which mode was more successful to transfer the knowledge of the experiment?

3 FINDINGS

3.1 Learning outcome (ten minute tests)

The second run of the experiment is conducted with 30 students in summer semester 2017. In year 2016 with 40 students the range of individual scores was from 12% to 85% for hands-on, and from 12% to 88% for the simulated mode. The distribution of all results was normal. As seen in *Table 1*, for three content areas (A to C) a weak effect towards benefits of the hands-on mode was measured. There was a slight trend demonstrating hands-on laboratory sessions led to a better knowledge acquisition compared to simulated experiments. Content area D showed no difference between the modes. [9]

Overall learning results of hands-on experiments were slightly better than those of simulated laboratories (weak effect, Cohen's d = 0.22), but the difference in performance was not statistically significant ($p=0.215>>0.05$). [9]

3.2 Student feedback

The student feedback results are based on all results of the first iteration and the results of content area A of the current ongoing laboratory in 2017.

(1) In hands-on mode more students expressed they gained new insights (81% vs. 55%, Cohen's d = 0.56, medium effect). Pearson’s correlation between mode and new insights was 0.28 and significant ($p=0.005$).

(2) A similarly large share of the students mentioned problems while conducting the hands-on experiments or their simulation equivalents (42% hands-on vs. 43% in simulation); Cohen's d = -0.02 is showing that there was no effect.

(3) The engagement in the simulated experiments was stated to be a small amount (8% of scale) more difficult (0.38 hands-on vs. 0.46 simulation). Cohen's d = -0.33 demonstrates a weak effect.

Table 1. Results of 2016 [9], Effect hands-on vs. simulated

Content Area	Sample Size	Percentage of points Mean Value **hands-on**	Percentage of points Mean Value **simulated**	Percentage of points Std. Deviation both modes	Effect size (Cohen's d) "hands-on led to better learning outcome"
A	37	38%	33%	16%	0.28
B	39	54%	49%	16%	0.32
C	35	52%	47%	18%	0.30
D	37	45%	45%	15%	0.04
all	148	47%	44%	17%	0.22

(4) Students who conducted the experiments in the hands-on mode rated the execution of the experiments a little more beneficial for their future professional life (0.58 hands-on vs. 0.55 simulation, Cohen's d = 0.19, very weak effect).

No significant correlations between these items were found except between (1) and (4), where Pearson's correlation was 0.41 ($p<0.001$) and Spearman's rho was 0.38. Looking at both modes separately, the correlation in the simulation mode was stronger (Pearson's r 0.52, p<0,001; Spearman's rho 0.52; N=49) compared to the hands-on mode (Pearson's r 0.23, p=0,115; Spearman's rho 0.14; N=48).

Due to a low response rate for this questionnaire (31%) in the first year (2016), in the second year (2017) the students were recompensed for their time to fill out a questionnaire. Additional 5% of points were added to the grading of the laboratory protocol, which makes it easier to reach the minimum level to pass the subject. In experiment A, which had already been conducted at the writing of this publication, the return rate increased to 77%.

4 CONCLUSIONS

4.1 Learning outcome

This study showed that the described methodology is applicable to focus on the comparison of two learning modes. By excluding many other influences on the comparison of the learning outcome, the results show only a small difference. The slightly better learning results of the hands-on mode are not significant. Some of the excluded factors might have greater impact on student learning than estimated previously. To get statistically significant results more data collection is necessary. This study is going on through 2018 at THI and the methodology will be tested at more universities with different types of students (e.g. international students, summer schools).

4.2 Online survey

The contrast between both modes in the student's subjective opinion about gained knowledge (1) is much more significant than in the objective results of the ten minute tests. The students' opinions show advantages of the hands-on mode: although one cannot determine the students understood more in this mode, one can conclude they gain more confidence in performing similar tasks. In a limited capacity, self-confidence can be considered beneficial for the students' further development by increasing their intrinsic motivation.

The correlation between (1) and (4) shows that students who claimed that they gained new insights also tend to believe that the execution of the experiment will help them in their future professional life. The weaker correlation between (1) and (4) in the hands-on mode suggests that even when the students think they gained additional insights, the students do not consider all of the insights relevant for their profession. Identifying these insights may be beneficial for the improvement of the experiments. Therefore, future surveys will ask for the most beneficial insights gained and whether they consider them useful for their future work outside the university.

Regardless of the learning mode, more than forty percent of the students think they do not benefit in their professional life (4) from the experiments. This is quite disappointing and leads to the possibility of asking for missing content students estimate as important for their future profession.

On one hand less students mention problems with the hands-on experiments (2), while on the other hand they feel the simulated variants to be more difficult (3). When taking a deeper look at the answers from the students, it becomes clear that these results are not correlated. A common mentioned problem was the lack of available measurement devices. Also problems tied to the use of the software could be considered as neutral, as the same software was used in both modes. The difference between the described levels of difficulty of the learning modes (3) raises the question for these reasons. At the time of writing we do not have a final conclusion on this weak effect. For the future evaluation of the study we will ask the students to describe the difficulty in a free text answer.

The actual methodology does not allow one to find correlations between individual learning outcome and student's feedback, as the standard online feedback form is not asking for the self-created code-word that was used in the tests. We plan to implement the new questions and this missing information to a new questionnaire in paper form and use it for the next iteration.

5 ACKNOWLEDGMENTS

This research was approved by the Faculty of Electrical Engineering and Computer Science of TH Ingolstadt and the College Human Ethics Advisory Network of RMIT, Melbourne.

Many thanks go to the laboratory engineer Sönke Barra for his assistance while planning, preparing, and conducting the experiments. The devices used in the laboratory were built from finance of the Faculty of Electrical Engineering and Computer Science at THI.

This research was not possible without students, generously ready to take part in the study to improve the learning outcome of future groups.

ABSTRACT
EPS is a one semester student-centred capstone programme designed by Arvid Andersen in Denmark, being currently offered by several European engineering schools. Its goal is to promote the development of scientific, technical and soft skills in students through multicultural teamwork and open, multidisciplinary project based learning. EPS, while an active learning framework, is focussed on problem-solving, communication, creativity, leadership, entrepreneurship, ethical reasoning and global contextual analysis. The School of Engineering of the Porto Polytechnic is an EPS provider since 2011, offering a 30 ECTU package with two-thirds assigned to the project module and one-third to project supportive complementary modules. A total of 138 students from 18 countries participated in the EPS@ISEP, while developing 28 multidisciplinary projects. Based on this experience, this paper identifies strengths, weaknesses and proposes ideas for the improvement of the programme.

Conference Key Areas: Skills and Engineering Education, Curriculum Development, Sustainability and Engineering Education

Keywords: Engineering Education, Project based Learning, Multicultural and Multidisciplinary Teamwork, Sustainable and Ethical Practices

INTRODUCTION
The challenges faced by engineering education are multiple and hard to address. Institutions and students are experiencing constant changes, including financial constraints, focus shifting and the need to develop new competences. Project and problem based learning approaches are particularly fitted for engineering education, but no longer provide *per se* all the competences required in future engineers, which

[1] Corresponding Author
M. F. Silva
mss@isep.ipp.pt

are expected to act in the global market, work in multicultural multidisciplinary teams, hold expertise in a specific engineering field and be proactive lifelong learners. This is the context that led to the creation of the European Project Semester (EPS) [1].

The EPS framework is a one semester student-centred international capstone project/internship programme offered to engineering, product design and business undergraduates, designed by Arvid Andersen [2]. EPS started in 1995 in Denmark and is currently offered by a group of 18 European engineering schools, from 12 countries, called the EPS Providers, as part of their student exchange programme portfolio. The goal of the programme is to prepare future engineers to think and act globally, by adopting project-based learning and teamwork methodologies, fostering the development of scientific, technical and soft skills. In particular, multidisciplinary and multicultural collaborative learning and sustainable and ethical development are pervasive concerns within EPS projects. The programme provides an integrated framework to undertake engineering capstone projects supported by a project-based learning methodology. Moreover, it focusses on teamwork and exposes students to cultural, scientific and technical diversity. The EPS package is organised around one central module – the EPS project – and a set of complementary supportive modules. The project proposals should refer to open multidisciplinary real world problems, empowering the teams for the conduction of their projects [3].

The EPS providers have discussed, agreed upon and posted on the EPS Providers site[2] the specification of the EPS framework – the so-called “10 Golden Rules of EPS” that an EPS provider must comply with: (*i*) English is the working language of EPS; (*ii*) EPS is multinational with a group size of minimum three and maximum six students, being four or five the ideal number; a minimum of three nationalities must be represented in each EPS group; (*iii*) ideally, but not necessarily, an EPS project is multidisciplinary; (*iv*) an EPS semester is a 30 ECTU package, the duration of which is not less than 15 weeks; (*v*) an EPS project has a minimum of 20 ECTU and the complementary subjects account for a minimum of 5 ECTU and a maximum of 10 ECTU; (*vi*) the main focus on EPS is on teamwork; (*vii*) the subjects included in the EPS must be project supportive; English and a basic crash course in the local language must be offered; (*viii*) the subjects must include Teambuilding in the very beginning and Project Management in the beginning of an EPS semester; (*ix*) project supervision/coaching must focus on the process as well as the product; and (*x*) EPS must have continuous assessment including an Interim Report and a Final Report. The different EPS programmes are not only compliant with this generic framework, but also with “diverse flavours”. There are programmes focused on engineering (most providers), business, product design or media and with different operational approaches. By default, EPS, as an engineering capstone programme framework, is intended for the final year of the engineering programme. There are programmes offered to 3rd year students (all providers), to 3rd and 4th year students (Polytechnic Institute of Porto) and 3rd, 4th and 5th year students.

Bearing these ideas in mind, Section 2 describes the EPS@ISEP programme. Next, Section 3 identifies the problems and strengths of this implementation and Section 4 proposes a set of improvement suggestions for near future implementation. Finally, Section 5, draws the main conclusions.

1 EPS@ISEP

The School of Engineering of the Porto Polytechnic (ISEP/PPorto) became an EPS provider in 2011 and has since welcomed 3rd and 4th year mobility students during

[2] http://www.europeanprojectsemester.eu

the spring semester. EPS@ISEP – the EPS programme provided by ISEP/PPorto – targets engineering, business and product design students and aims to prepare them for their professional life by fostering the autonomous development of scientific, technical, personal and social skills

The EPS@ISEP programme is a 30 European Credit Transfer Units (ECTU) package structured in six modules: 20 ECTU assigned for the project module and 10 ECTU for complementary modules: Project Management and Team Work (2 ECTU), Marketing and Communication (2 ECTU), Foreign Language (2 ECTU), Energy and Sustainable Development (2 ECTU) and Ethics and Deontology (2 ECTU). The latter are project supportive seminars, oriented towards the specificities of each project, focussed on the development of the soft skills essential in the training of twenty-first century engineers: communication (including technical-scientific English) contributes to the development of the project deliverables; project management focuses on task identification, human resource allocation, task planning and scheduling, resource management, plan enforcing and eventual rescheduling; sustainability addresses the ecological footprint; ethics and deontology analyses the ethical and deontological concerns; and marketing tackles the market analysis, segmentation and positioning of the prototype [4]. Furthermore, there is also an Arduino crash course to provide students with basic knowledge about this simple control platform. Figure 1 presents the EPS@ISEP schedule and illustrates the concretization of golden rules *viii* and *x*.

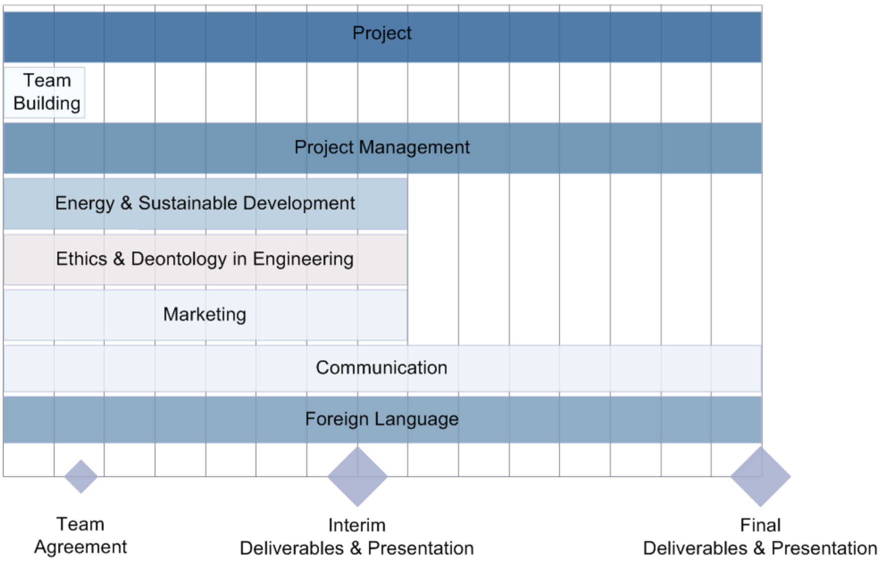

Fig. 1. EPS@ISEP schedule

Before the beginning of the semester, a set of project proposals regarding real world problems are collected, each one with a specific client, with a strong focus on sustainability, to raise the student's awareness to the problem, and in multidisciplinary topics, so each team member can contribute to the project with his/her previous knowledge and background experience. The origin of proposals ranges from industry, services, R&D institutions or the school itself. The proposals tend to be multidisciplinary problems, i.e., require the integration of multiple technical and scientific competences. A proposal defines the problem/challenge to tackle, the minimal set of requirements, mostly mandatory directives and standards, and the maximum budget. This type of proposal directs the team towards the design thinking stages and, then, towards the development and operation stages of the capstone project/internship. As all proposed projects are open ended, team discussions about the possible solutions provide an opportunity for the students to expose their different beliefs and values, in a multicultural setting. Depending on the complexity of the projects, the average cost of an EPS@ISEP project is approximately 200 €.

Before the start of the semester, each student is asked to fill a Belbin questionnaire, which will be used to identify the individual teamwork profile and design of teams according to rule *ii*. According to the EPS rules, not only the teams must incorporate students from different fields of expertise and nationalities, but team building activities must be offered to allow team members to discover and perceive the existing cultural, scientific and personality differences. One of the first tasks team members are faced with during team building activities (rule *viii*), is to define their own set of conflict resolution rules – Team Work Agreement – using the mechanism proposed by Hansen [5]. The resulting document is signed by all team members and archived in the team folder. Next, the teams select the project of their choice from the list of project proposals available and start their learning journey by conducting studies on marketing, ethics, deontology and sustainability together with scientific research (a state of the art analysis of the problem domain) to decide on the structure design & materials, as well as on the system design & control system.

EPS@ISEP adopts a unique supervision model where a panel of multidisciplinary experts, consisting of teachers from various study fields, acts as a consulting committee (Figure 2). Every week, this panel meets with each team for about 40 min.

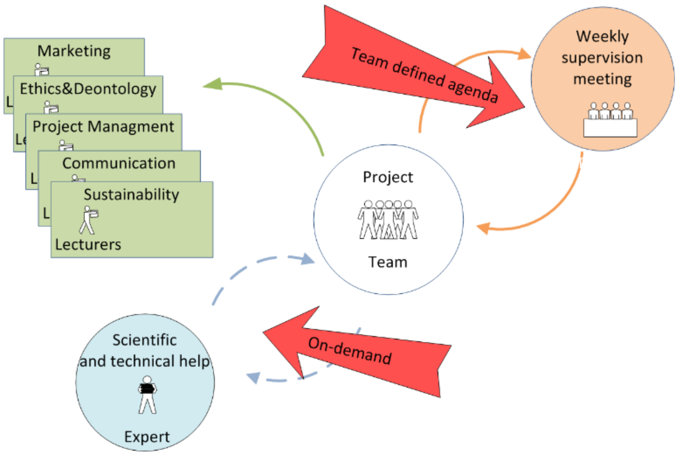

Fig. 2. EPS@ISEP model of student supervision

In the meeting with the panel, the teams conduct the meeting, and only the topics previously specified by the team in the wiki agenda are discussed. In this meeting, the teams are challenged to explain and justify any decisions taken during the previous week (shared in advance on the project wiki) and motivated to explore further. In order to be effective, the coaching panel is aware that it is interacting with students from diverse scientific and cultural backgrounds as well as that it must provide prompt feedback. In addition, the teams hold weekly meetings with their direct project supervisor(s) to promote further brainstorming, debugging, assembling and testing of the project. The teams can take the initiative to propose additional coaching meetings.

Assessment drives learning and hence a good assessment design is the key to effective student development [6]. EPS@ISEP uses the assessment scheme proposed by Hansen [5]. Assessment occurs twice during the semester and contemplates self and peer (S&P) and supervisor assessment (SA). The S&P assessment considers the quality and quantity of the technical contribution, openness to others ideas, teamwork performance, leadership, attitude and initiative shown [7]. The SA assessment reflects both team performance as well as the individual performance of each student. The interim assessment is intended to give individuals and teams feedback about their performance so far, from the point of view of their peers and of the supervisors. The supervisors use the assessment to monitor team working and to give constructive feedback and advice where needed [7].

The teams must produce several deliverables, including the project wiki, report, video, paper, manual, brochure and a proof of concept prototype. The report structure (provided beforehand) includes as mandatory sections the introduction, state of the art, marketing, sustainability, ethical concerns, project development and conclusions. Some chapters are produced and refined within the corresponding complementary modules. The structure and presentation of the deliverables are addressed in the communication seminar. The wiki is a key tool to the EPS process since it acts as a collaborative work platform and as the project show case.

2 REFLECTION ON EPS@ISEP

Since 2011, EPS@ISEP has welcomed 138 students from 18 countries, as depicted in Figure 3. These participants successfully conducted 28 projects.

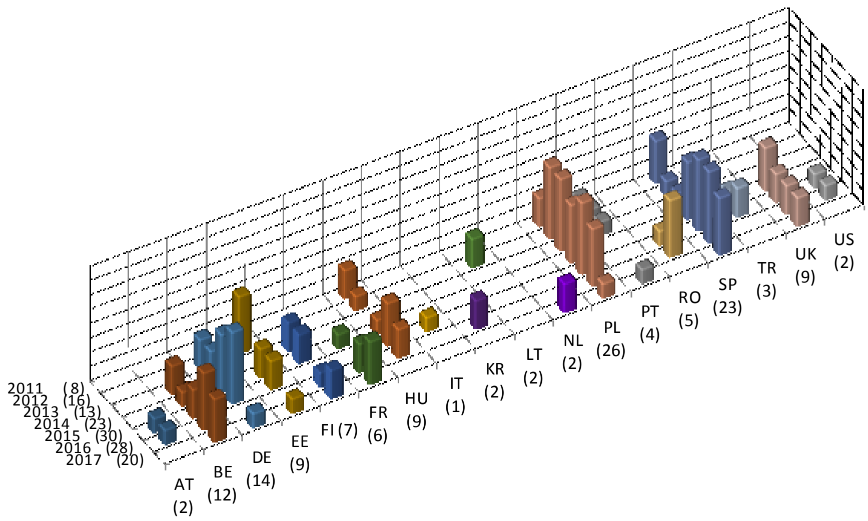

Fig. 3. EPS@ISEP: Number and nationality of students

The scheduled classroom activities involve thirteen teachers from seven ISEP departments and account for a total of 472 h/semester. Dislocated EU students are supported by EU Erasmus+ mobility grants, typically covering one round trip and the accommodation costs. These figures allowed the identification of several strengths, but also weaknesses related with the programme management and costs, the students profile and their motivation and the teaching and support staff.

2.1 Programme Management

Concerning the managerial aspects, the programme involves a 470 h of teaching and a dedicated room is allocated to all activities during the entire semester. However, since this programme implements hands-on practical training, there is the need to use different laboratories, mainly related to the development and construction of the prototypes. Typically, due to the wide range of the problem domains, there is the need to use several laboratories from different departments, *e.g.*, the mechanical, electrical, electronics and chemistry laboratories. This dependency presents problems related with the authorisation and availability.

Another aspect related to this topic is the financing of the projects. While initially the projects were financed by ISEP, nowadays they are financed by sponsors, clients, prizes, organisation of events and the fees of international (non-EU) and free mover students. The materials and components acquisition is a cumbersome process, due to the requirements for public procurement of goods and services in Portugal. The teams participating in the EPS@ISEP provide the supervisors with their list of materials and suppliers. These lists must be thoroughly inspected, to check if the suppliers fulfil the existing acquisition rules, and submitted to the financial department for approval. After authorisation, orders are placed and, typically within a week, the materials are received and delivered to the teams. During this process, teams often suggest suppliers which do not fulfil ISEP's acquisition rules, typically companies operating on the Internet, such as Amazon, eBay or Alibaba, and despite repeated warnings, make non-authorised purchases.

There is also a problem with the grading system. The EPS grading system privileges the process instead of the product, but this presents some drawbacks, since it tends to penalize good, hard-working, students who belong to weak groups, and favour weak, non-working students, participating in strong groups. This aspect has led to situations on which hard-working students feel wronged and lazy students feel lucky. These students, after returning to their home institutions, advertise against and in favour of the programme, respectively, preventing the application of students from these institutions with the desirable profile in subsequent years.

2.2 Student Issues

Regarding the students, there are four main drawbacks: insufficient mastery of the English language, insufficient technical-scientific background knowledge, pending academic activities at home school and wrong motivation for participating in an exchange programme. Although applicants must provide a B2 Common European Framework of Reference for Languages (CEFR) level of English, in some cases their actual level of English is below. The second aspect is related to the fact that some students enrol without sufficient technical-scientific background knowledge. In other cases, they have not yet accomplished the necessary 150 ECTU to enrol in a capstone/internship module and still have pending academic at their home schools. Such activities, *e.g.*, exams, are highly disruptive and involve returning for a few days. This is particularly inconvenient when it occurs in the last months of the semester, a period of heavy workload involving the assembly and test of the prototype and the subsequent preparation of the final deliverables. Finally, there are still students with the wrong motivation to participate in an exchange programme, *i.e.*, focussed on travelling and recreational activities rather than on the personal growth and international multidisciplinary teamwork offered by EPS@ISEP.

To minimise the first problem, all students are asked to send a B2 CEFR level English certificate as part of the application documentation. Regarding the second and third issues, the acceptance letter, sent to the accepted applicants and their home institutions, specifies the programme acceptance rules, stating that students must not have pending activities at their home schools during the spring semester, nor have less than 150 ECTU accomplished at the moment of their arrival. Unfortunately, there are still students and partner schools disregarding these rules.

2.3 Staff Issues

Although the programme involves, on average, around 20 students, thirteen teachers and account for a total of 472 h each semester, there is no support staff to help manage the programme activities. This implies that all bureaucracies inherent to the programme, as well as student problems must be solved, mainly, by the team of supervisors, which is a time-consuming activity. The only exception is the mobility documentation processed by the International Office.

Concerning the seven project supervisors, it should be mentioned that coaching EPS students is an additional activity involving large amounts of unaccounted time and effort. However, despite this, the team of supervisors has worked together with most teams to publish a project paper on reputed international conferences and, in some cases, even in international journals with peer-reviewing.

Finally, the six project supportive module teachers are from distinct departments and it is, sometimes, difficult to keep the same teachers between editions. Also, some of these teachers are not fully aware of the particularities of the programme and of its objectives, and have some difficulty in organizing and teaching their modules in a way that is fully supportive of the project that the students are developing.

3 IMPROVEMENT SUGGESTIONS

The first improvement suggestion is to allocate a laboratory/room equipped with basic consumption materials, tools (mechanical and electrical/electronic) and equipment. This laboratory should also be equipped with basic machines for wood working since several project prototypes have been developed in wood. Finally, this space should include a technician to support the students during the development of their project prototypes and conduct, whenever necessary, the purchase process.

Regarding the use of the budget allocated to the project, an effort should be made to have most of the project proposals sponsored by companies / institutions outside of ISEP. In these cases, what has been negotiated with the companies if that the acquisitions are performed directly by the team of supervisors, the receipts have the data from the companies, and the expenses are latter directly reimbursed to the people that acquired the materials (teachers or students), without the inherent bureaucracy.

In relation to the EPS grading system, the problem is difficult to tackle since a decision should be made among the providers to change it. Anyway, the supervisors should have the possibility to “bypass” the “regular” grading system under justified circumstances, *i.e.*, whenever they believe any student has been unfairly assessed.

Concerning the problems related to students, it is impossible to assess their motivation, English and technical knowledge before they arrive. This can only be solved with the cooperation of the partner schools. In particular, it is easy to ensure that applicants have accomplished at least 150 ECTU and do not have pending exams. In addition, this should be discussed and agreed among the providers.

Finally, internally, an effort should be made to consider the actual number of teaching hours involved in the coaching of EPS students and the departments should assign teachers motivated to foster multidisciplinary project-based learning.

The authors recognize that some of these ideas are difficult to implement, but must be considered if the programme is to be improved.

4 SUMMARY AND ACKNOWLEDGEMENTS

The EPS student-centred learning process is based on promoting the autonomy and responsibility in the teams, adopting technical and scientific coaching and offering project supportive and soft skills complementary modules. This process drives the teams to design and develop a concrete prototype and produce multiple deliverables, while learning to manage the project, to study the state of the art in the different fields of the project, to create a marketing plan, to work together and to justify all design, materials and development decisions based on the analysis of the sustainability, ethics, scientific and technological aspects. However, the objective of this programme is more ambitious than just expecting the students to implement prototypes – it is also to make them contribute with their distinct visions of the problem to a common consensual solution. This process is not always easy, since at this educational level the students are not used to collaborate with peers from different nationalities (implying distinct cultural backgrounds) and from different study backgrounds (engineering students tend to think differently from business and product design students). Given these ideas, this paper described the EPS program, reflects on its implementation at ISEP and proposes improvement suggestions regarding the EPS@ISEP implementation.

This work was partially financed by the ERDF – European Regional Development Fund through the Operational Programme for Competitiveness and Internationalisation – COMPETE 2020 Programme within project POCI-01-0145-FEDER-006961, and by National Funds through the FCT – Fundação para a Ciência e a Tecnologia (Portuguese Foundation for Science and Technology) as part of project UID/EEA/50014/2013.

Sustainability accreditation in engineering education:
Comparison between Danish and French contexts

ABSTRACT

Even though international organisations and engineering professional organisations recognise the need for engineering education institutions to prepare future engineers to contribute to a sustainable society, there are considerable differences in the push from national regulations and accreditation systems to ensure engineering education for sustainable development (EESD). This system paper presents an outcome of collaboration in the SEFI working group on Sustainability in Engineering Education set out to compare the accreditation frameworks for engineering education in two European countries, Denmark and France, with specific attention to the integration of sustainability. The study outlines the range of accreditation frameworks in terms of their call for sustainability, from sustainability as a possible (yet not explicitly formulated) approach to contextualise engineering in a societal perspective, to sustainability integration as an explicit accreditation requirement.

Conference Key Areas: Quality Assurance and Accreditation

Keywords: Engineering Education, Sustainability, Accreditation frameworks

1. INTRODUCTION

International organisations and engineering professional organizations recognize sustainability challenges and complex contexts that engineering students have to address. For example, the European Society for Engineering Education (SEFI), through the working group on Sustainability in Engineering Education stresses the need to implement sustainability in engineering education. The overall aim is to equip engineers with knowledge, competences and skills such as systems thinking, critical thinking, problem solving skills, communication, teamwork, interdisciplinary knowledge, flexibility, and adaptability, to address sustainability problems.

Even though, the engineering education for sustainable development (EESD) societies have achieved much in the last decades (by establishment of thematic conferences, journal publications, working groups, etc.), sustainability integration in engineering education has been slow and behind the needs. Integration of sustainability in engineering education responds to local conditions, resources and national accreditation systems where different frameworks are adopted and differ from country to country.

This system paper presents an outcome of collaboration in the SEFI working group on Sustainability in Engineering Education of examining the role of accreditation in supporting the integration of sustainability in engineering education. We have done that by comparing accreditation frameworks and standards from two European countries, France and Denmark.

The story takes point of departure in the Danish system of Accreditation of Engineering Institutions and Programmes, which illustrates a system with high attention to the quality management process and an emphasis on overall accreditation criteria. The focus then shifts to France, illustrating a case with a similar high focus on Quality management aspects but with more specific accreditation criteria for Engineering Education for sustainability.

2. ACCREDITATION OF ENGINEERING EDUCATION IN DENMARK

In Denmark, The Danish Accreditation Institution is the specific organization responsible for accrediting higher education, including institutions and programmes. The purpose of the Accreditation framework is formulated in a quality management perspective with focus on development whereas the quality assurance and control is to be seen as inputs to this process, as noted by the Danish Accreditation Institution [1:3].

“The purpose of the accreditation system and institutional accreditation is to strengthen the work carried out at education institutions to develop programmes to an increasingly high level of academic quality and relevance.”

There are two different levels of accreditation in Denmark – institutional accreditation and accreditation of specific programmes. In the following, we will focus on presenting the different types of accreditations and the criteria for the Danish Accreditation framework. For more information about the accreditation process, please see [2] and [1].

2.1 Different levels of accreditations

Accreditation processes take place periodically and it is done at an institutional and a programme level. The accreditation guide refers to five main criteria [1][3]:

- I: Quality assurance policy and strategy; e.g. goals for overall quality assurance and development and also inclusiveness of all educational programmes
- II: Quality management and organisation; e.g. the requirement to include all relevant actors and management levels.
- III: The programmes' knowledge base, e.g the relevance and quality of the related academic environments and staff development.
- IV: Programme level and content, e.g. compliance with the Danish qualification framework for higher education programmes and on-going evaluations on program level.
- V: Programme relevance, e.g. ensuring that the programmes reflect the needs of the labour market and include external actors involvement in development of programmes.

On the programme level there are also five criteria [3]:

- I: Demand and relevance including employability for existing educations and the relevance for the labour market (relates to Criteria V in the Institutional accreditation).
- II: Knowledge base including research base and relevance (relates to Criteria III in institutional accreditation)
- III: Learning goals e.g. whether the learning objectives for the education is aligned with the Danish qualification framework (relates to Criteria IV in the Institutional accreditation)
- IV: Planning and implementation including the structure and pedagogical quality of teaching.
- V: Internal quality assurance and development, e.g. focusing on evaluations of the actual practice (relates to Criteria II in the institutional accreditation)

If an institution has a positive institutional accreditation, they have the opportunities to establish new programmes and new local provision of programmes when they have been pre-qualified (only in relation to aspects of programme criterion I) and approved, and to make adjustment to existing programmes. If the institution on the other hand has a conditional accreditation, all new programmes and local provision of programmes must be accredited before they are established, and a plan is drawn up for improving the conditions to apply for a positive accreditation. If the institutional accreditation is refused, the institution cannot establish new programmes or local provisions of programmes, and existing programmes must be accredited in accordance with a rota plan. Thereby, a huge interest exists in obtaining institutional accreditation.

2.2 Sustainability in the accreditations framework?

In regard to the more specific programme level content (Criterion IV-institutional accreditation; Criterion II-III – programme criteria), a reference occurs to the Danish qualification framework and the Act for Bachelor and Master Educations at Universities.

The Danish qualification framework [4] specify generic qualification levels at Bachelor and Master level, as for example interdisciplinary collaboration, however with no specific mentioning of specific cross-cutting subjects as sustainability. On the contrary, subject(s) are mentioned in indefinite articles only. Neither does the programme criterion considering learning goals specify any requirements to content besides the relevance to the Danish qualification framework.

The Act for Bachelor and Master Educations at Universities, however, specify in relation to Engineering type of education that [5]:

"The candidates within the field of engineering have the purpose to qualify the student to solve complex technical problems, design and implement complex technological products and systems in a societal context"

However, no clear indication exists on how this relation to the societal context should be framed.

Thereby, neither the Danish qualification framework nor the Act for Bachelor and Master Educations in Engineering provide any mentioning of sustainability, and as the accreditation framework does not move into more detail considering learning objectives in different knowledge domains, a positive accreditation in this framework does not assure integration of sustainability in engineering education. Rasmussen [6] has characterised this as a paradox as higher quality was introduced as the goal in the political agenda, but there is no real direction for this quality improvements, as education does not have to do anything specifically, they just have to do it in a qualified manner. Furthermore, institutions have to document in detail what they do.

The current accreditation framework, on the other hand, provides Danish universities with a high degree of freedom in terms of curricula design, as long as they can argue for relevance from an employability perspective. In relation to sustainability education, this means that sustainability learning perspectives can be framed and closely related to different disciplinary domains. Currently, due to the urgent demand to get institutional accreditation, there is, however, a risk that engineering education for sustainable development is not prioritised.

3. SD IN EE CURRICULA IN FRANCE

The "Commission des Titres d'Ingénieurs" (CTI) realizes, in a mandatory way, the accreditation of Public and Private Engineering Universities in France, and on request abroad. This agency is a member of ENQA (European Network for Quality Assurance), this means that CTI satisfies some important requirements such as adapting its accreditation criteria to the evolutions of society and demands of its stakeholders.

Social responsibility is considered an important challenge for engineers, moreover, besides CTI's criteria concerning technical skills, there are strong criteria that concern teaching of soft skills: in French accreditations, human and social fields of teaching must represent about 25% of the programs.

Six years ago, the criteria concerning SD were not put in the mandatory ones, we had written a document called “Analysis and Prospective” which was available on our website to help institutions in their evolution towards SD. Then, they became part of the mandatory criteria that are in “Références et Orientations” (R&O) which is the reference book for French Accreditation [7].

The fact that CTI is a parity based organization composed of an academic college and a socio economic college is also a determinant factor: very often, norms concerning SD are already on application in companies, this made professional members very receptive to the problems linked to the domain of SD very soon.

3.1 The different attempts concerning SD in France

In France, the problems concerning SD have also been soon taken in account by students, as well as by organizations of deans such as Conférence des Grandes Ecoles (CGE) and by Ministries, some of them trying to act as positive lobby. CGE is still very active in this field, having recently edited a guide of skills concerning SD and its reflection group is in charge of the French evolution of the SUstainable LItteracy TEst.

In 2007-2008, the network of French students for SD [8] realised a survey among the students (15 000 of them gave their opinion about SD and SD education) in order to make propositions resulting from these statements and expectations. The outcome was that teaching of SD was either absent or very specialised in French education. The students expected more active pedagogies connected to the “real world”. One of their proposals was to make campuses exemplary and to define a minimal curriculum that should be taught to everybody. However, due to the autonomy of universities, it revealed very difficult for this group to make institutions evolve quickly.

A first attempt to evolve faster has been the Green Plan, perhaps because it is based on a law but also because it includes many of the aspects considered in previous attempts in Europe. According to a French law, the “Loi de Grenelle” of 2009, the Higher Education Institutions have to elaborate a Green Plan which is a plan intended for sustainable development including environmental preoccupations but also a social and economic one.

The success of “Plan Vert” needs:

- the SD strategy to be elaborated
- the institution mission to dedicate a person responsible for the animation, the setting and the evaluation of the SD process; this person must have human and financial resources

A framework has been defined after promulgation of “Loi de Grenelle”, it has been named Green Plan Reference system [9]: it is a toolbox helping to define a SD strategy, its steering and its self-evaluation. 5 dimensions are to be considered for elaboration of the “Plan Vert” of an institution: Strategy and governance, Teaching and education, Research, Environmental management, Social policy and Territorial management.

3.2 CTI requirements

In February 2014, CTI, considering that teaching social responsibility to engineers was a critical point for society and a duty for engineering institutions, decided to include immediately SD not only in the intended learning outcomes as it was previously, but also in the description of the global policy of the institution: this was an important evolution of the accreditation criteria [10].

The strategic guidance note of the institution being evaluated should include the orientation chosen by the institution regarding SD and particularly quote the Green Plan that describes the institution’s strategy, its implementation and evaluation. The strategic guidance note is an important part of the self-assessment report because the institution’s administrative council votes it, and when this institution is part of a group of faculties, the university council also votes it.

CTI strongly wishes that institutions really integrate SD through curricula in the education of engineers but also apply the principles of SD in their own management, working in an exemplary way.

When an institution is accredited or reaccredited, the implementation of Green Plan has to be explained within the quality process of the institution. CTI has quoted eight dimensions of operational actions to be verified during the evaluation process:

- strategy and governance
- social management and local integration
- environmental management
- research
- curricula
- documentation
- industrial rooting
- quality management and continuous improvement

CTI stresses that a specific innovative active pedagogy has to be put in place for SD, this pedagogy of action puts the engineering student in the situation of finding and building solutions to “real world” matters. CTI also specifies that the recruitment of students must guarantee diversity according to a policy concerning chances equity.

Learning outcomes

However, regarding the curricula, the major point of the accreditation audit is the observation by the experts of the expected learning outcomes that the graduates must possess at the end of the curriculum.

Three of them are in direct relation with SD:

- The capacity to take into account the stakes of relationships at work, of ethics, of safety and health at work
- The capacity to take into account environmental challenges especially by application of principles of SD
- The capacity to take into account society’s stakes and needs.

During the audit of programs, CTI’s members have to check the conformity of these LO but also how they are really assessed.

3.3 Results

The first results were, however, not completely satisfactory, because very often, either the dean of the school or either the experts in charge of this audit did not really realize that criteria had changed or did not know how to act for SD.

In February 2016, CTI decided to go further. Because some new points of view concerning engineering were out of the traditional field of investigation of CTI, and because those points presented some difficulties, not only for schools but also for experts, we decided to put in place what we call “Focus” on SD. A focus is a specific point developed by the institution in 3 or 4 pages that will be delivered by the institution together with its Self-Evaluation Report [11].

The results were really satisfying and were broadcasted to all institutions.

4. CONCLUSION

In this paper, we have provided an example of the Danish Accreditation framework, which, comparable to other quality management frameworks, focuses on developing processes for quality control, assurance and integration. Crosscutting subjects of broader societal concern, like sustainability, are not even mentioned. Education for sustainability is to be defined by the institutions in an employability perspective.

If the universities take the lead in pushing for sustainable development, the degree of freedom to specify sustainability learning outcomes, which are aligned with the profession, might be an advantage. In other cases, it can just be concluded that there is only a vague and rather indirect push for education for sustainability in the Danish accreditation and legal framework for higher education. The integration of sustainable development as part of the qualification profile of Danish engineers, on the institutional as well as on programme level, is thereby left to the educational institutions to act on.

The CTI work in France shows how sustainability can be more explicitly included in the accreditation criteria. However, the lesson learned is also that the process from explicating sustainability in the accreditation criteria to actual change in the institution has to be carefully facilitated. The France case also points to potential future elaborations as to consider sustainability introduced in the management of the institutions as well as in the learning outcomes of graduates. These new recommendations have already made considerable changes at the institutions in France. A question for further research is how this change process can inspire similar change processes in Denmark, as well as in other European countries. The first step, however, is political will to push for sustainable development thought accreditation of Engineering Education.

ABSTRACT

In our increasingly connected and global society, it is necessary for students to have interdisciplinary and intercultural skills to work with people from all over the world, for successful knowledge transfer, and for life-long-learning and encouragement of collaborative skills. Since 1998, a German technical university developed and continually improves upon a project-oriented and problem-based learning (PPBL) model that integrates both teamwork and systems thinking (engineering design) into an intensive, immersive project week. This model was then transferred to a newly formed Mongolian university. At the beginning, German academic staff introduced the Mongolian faculty to the PPBL model and taught the course for two years. For full empowerment and transfer of procedural and informal knowledge of the PPBL model, Mongolian academic staff attended a week-long workshop to learn and adapt the German model. This past year, the course was taught by Mongolian staff with mentoring from the German faculty. Our current snapshot shows that the transfer of the German PPBL model to a Mongolian university is on the path to be successful. Based on our experiences, we propose a feedback style which focuses on positive reinforcement of team resources in social environments where participants are not used to constructive feedback.

Conference Key Areas: Continuing Engineering Education and Lifelong Learning; Sustainability in Engineering Education; Engineering Skills

Keywords: PPBL model; sustainable knowledge transfer; intercultural experiences; cultural adaptations

1 INTRODUCTION

As we are living in a progressively complex and globally connected world, there is an increased need for students with project skills (teamwork and system thinking) and knowledge transfer between individuals, disciplines, universities, cultures, and countries to further encourage collaborative skills and life-long learning.

Accelerating global change includes socio-economic, earth system, and technological developments such as “Industry 4.0” and “big data”[1-4]. This has led to three major trends that impact and change the workplace: informatization, globalization, and financialization[5,6], which further lead to an informational capitalism with the specific characteristics of a “knowledge society”[7-9].

As a result, work has become organized in a more temporal, network-like structure and more knowledge-intensive[5,6]. Highly qualified workers should be creative, socially competent, and self-organized and be able to move easily between the “real” and virtual worlds along with knowing and efficiently using the related communication channels needed for these transitions[10].

The increase of complexity and flexibility at the work space leads to a continuous entanglement of working (doing) and learning[11]. Employees need to be proactive and adaptable with twenty-first century skills to be successful within this setting[12] and requirements along with the ability and readiness for lifelong learning[13,14].

Along with these developments and trends in the workplace, learning in higher education focuses on the approaches of constructivism[15] and connectivism[16,17]. Therefore, learning environments should be designed that will prepare students fully for the future, an increasingly interconnected, global world and workplace. These learning environments typically combine learner-centered, knowledge-centered, assessment-centered, and community-centered aspects[18], and goes hand in hand with a blurring of the separation between formal and informal learning[19]. These trends in higher education learning highlight and support “pervasive learning”[20] in “enabling learning environments”[21].

Project-orientated learning and design courses enables concurrent teaching and learning of teamwork and systems thinking (application of design) skills in a structured learning environment that combines aspects of their future workplace. This allows students to witness and experience the “messiness” of real-life industrial and teamwork problems, and has been shown to have long-term, positive impact on teamwork skills[22-26].

Drawing from this background, this paper discusses an innovative learning environment developed at a technical university in Germany and further describes the knowledge transfer of the concept to a Mongolian university. First, we will shortly introduce the project-oriented and problem-based learning (PPBL) model developed as an interdisciplinary, international project course. Next, we will report on and reflect upon our intercultural experience with our cooperation with a Mongolian university, and the shared learning experience of transferring the PPBL model as well as practical, informal knowledge to their academic staff.

2 GERMAN PPBL MODEL

The German PPBL model has been detailed previously[27-32]. Shortly, this model was originally developed in 1998 in collaboration with the Center for Educational Development at the German university as a monodisciplinary intensive, immersive, one-week design project course for first year students in mechanical and process engineering. In 2011, the mondisciplinary course was expanded and transformed into an interdisciplinary course and in 2012 was further expanded into an international, interdisciplinary course with German and American engineering students.

The core tenant of the German PPBL model is the concurrent teaching of teamwork and design skills in an innovative learning environment where students apply these skills through practice and reflection. The task teams are given is designed to be open-ended, complex, challenging, and similar to a team-orientated industrial project, and this leads to each team having finite resources e.g. time and knowledge that they must manage throughout the week to develop a solution. To support and not overwhelm the students, a support system consists of the following elements was developed:

- Team advising. Team advisers are mostly students of sociology, psychology, and pedagogy who have been intensely trained by the Center for Educational Development in team building and team competences. They establish standards and criteria of behavior modeled by professional (industrial) teams emphasizing team working techniques, communication, and problem solving e.g., discussion, moderation, visualization, through self-reflection, team-reflection, team-feedback, and additional feedback from the team adviser. The team advisers co-advise teams tandemly with a technical adviser.

- Technical advising. Technical advisers are academic staff who follow the principle of minimum help[33] and the Socratic questioning method. This means empowering teams with as minimum help as possible but as much as needed or necessary. Technical advisers give mostly general strategic, problem solving, and design process advice along with motivation and content-specific advice as needed.
- Help desk. The help desk is a scientific research resource for teams and is also orientated by the principle of minimum help. It follows the motto of, “Good answers to good questions,” meaning teams need to have pre-formed questions for the help desk and not just ask for a solution and/or if they are correct or wrong about an idea.
- Experts. The teams have the opportunity during the middle of the project week to consult with outside experts, typically professors and/or industrial experts. Each interview is approximately 10-15 minutes so each team needs to be prepared for these consultations.
- Jury panel. At the end of the week, teams present their final solution to a jury panel of experts, professors, etc.
- Project leaders and supervision. The project leaders not only organize the project week, develop the task(s), train the team and technical advisers and help desk members but also supervise and provide technical and didactic support to all the staff during the project week as needed.

The positive, value-added impact of this PPBL model at the German university has previously been shown[27-32]. Shortly, students are meeting the desired learning outcomes of the model including learning teamwork skills, disciplinary skills, and interdisciplinary integration along with increasing intrinsic motivation for their further studies.

3 TRANSFER OF PPBL MODEL – INTERNALIZATION OF STUDY PROJECTS

In 2014, the German PPBL model was expanded once more and brought to a Mongolian university. The model was transferred following a scaffolding procedure from introducing the Mongolian staff to the project to empowering them to identify, adapt, and make the model their own. The first step introduced them to the project and model with German staff traveling to Mongolia to lead the project week and perform the major roles. This was followed by Mongolian staff attending a workshop held at the German university to train them in the major aspects of the PPBL model, followed by mentoring the Mongolian staff during the following project week at their university. The last step will be for the Mongolian staff to continuously improve and implement the model for their needs.

3.1 Step 1 – Experiences in Mongolia

For two years, the German PPBL model was implemented with German academic staff maintaining the major roles, i.e., team and technical advisers, experts, and help desk, while the Mongolian academic staff had more supporting roles, i.e., organization at the university level and experts. Tasks similar in scope to German project courses were developed but adapted with relevance to Mongolian society, e.g., development of an autonomous robot that is capable of collecting and sorting litter alongside the road and removal of nitrogen oxides from diesel exhaust using urea. Due to the smaller size in comparison to the German project courses (two groups, each with approximately 10 students), the help desk and expert interviews were not utilized, but German staff were available to meet with groups as needed to discuss solutions and problems as they arose. Mongolian students were in their first semester of studies in mechanical engineering, environmental engineering, or raw materials and process engineering, but all three programs have the same curriculum for the first four semesters.

One major difference seen between the original German PPBL model and the one adapted is the role and the level of interaction of the technical adviser. In the German PPBL model, the principle of minimum help[33] guides the interactions of the technical adviser with it being a more passive role unless asked specific questions by the team and providing more strategic advice and motivation than subject-intensive advice. However, it was experienced that the project courses led by the German staff that the technical adviser needed to take on a more active role in the teams by providing subject assisted learning, direct information about design approach, and more general motivation.

There is a standard evaluation procedure developed for the underlying, core PPBL model which consists of three main parts. One part is the daily reflection with the student groups for their learning process. Another part is the daily review with the team and technical advisers and project leaders for the advisers' learning process and for learning adjustments that need to be made in the student groups. The third part is the final evaluation for improving the model for the next year(s). For the the first two Mongolian cohorts, there is only data for the 2014 cohort, but we do not have permission of students (small cohort of approximately 20 students) to publish. It was only gathered and used for internal use, e.g., improving the learning process (of students, advisers, and project leaders) and improving the model for future courses.

3.2 Step 2 – Workshop in Germany

After two years of leading the course at the Mongolian university by German staff, a training workshop was developed to fully transfer the PPBL model and enable the Mongolian university staff to learn and adapt the model. The workshop followed a constructivist approach with half of the day working directly with the trainers and the afternoons were for self-directed study where the content could be deepened by additional literature reading, guided reflection questions, and/or adapting and transferring the learned content to their own university. The learning outcomes from the workshop were as follows: The Mongolian university staff

- have received an overview of the organizational standard procedure of a project week,
- are empowered to qualify and implement the support system, mostly consisting of team and technical advisers,
- have practically applied the approach of constructive feedback as an intervention method at a team level as a team adviser and have practiced the steps involved in the principle of minimum help[33] as applied by technical advisers, and
- have reflected upon the concept and the connected challenges to generate ideas on how to adapt and sustainably implement the German PPBL model at their own university.

The workshop was broken down into five complementary building units.

- The first unit gave an overview of the German PPBL model including the concept, procedure, support system, and critical success factors regarding organization and didactic preparations for study projects grounded in the broader scope of project-orientated and problem-based learning.
- In the second unit, the participants learned about the didactic approach of team advising including goals, tasks, attitudes, settings, and competences of team advising as well as how to recruit and train team advisers. The method of constructive feedback as intervention was introduced, applied, and feed-backed by the trainers.
- Equivalent to the second unit, the third unit dealt with technical advising including goals, tasks, attitudes, settings, competences, and how to recruit and train future technical

advisers. The main method of technical advisers, the principle of minimum help, was trained and feed-backed by the trainers.

- The fourth unit combined and introduced team and technical advising as a tandem partnership, how advising is a collaboration between both advisers, the importance of communication between the advisers, and the kick-off to the project week.
- The last unit discussed further agents of support, such as the help desk and experts during the expert interviews, the project leadership, and supervision. The workshop ended with a general discussion crossing all topics and evaluation of the workshop itself.

A final reflection and evaluation with the participants indicated that they had learned how to adapt the German PPBL model structure at their university, how to manage a team, and how to implement the new teaching methods.

For future intercultural workshops, it is recommended based on our experiences to always remain in constant exchange with participants about their needs, experiences, and wishes to keep the material and topics relevant and suited for their world along with giving participants enough time to discuss, adapt, and implement learned knowledge. A critical success factor is using the pre-knowledge of participants to systematically build further practice and theory.

Generally constructive feedback is a significant tool for project teams to reflect upon their actions to constantly improve them. During the workshop, it was learned that the approach of giving and receiving feedback is unusual in Mongolian culture and tradition, even in everyday life communications. Nevertheless, the Mongolian staff were convinced that it would be fruitful for their students to learn and implement feedback during the study projects. The procedure needs to be adapted to be acceptable, culture-sensitive, and be valuable to Mongolian students. One needs to reflect on different feedback styles, traditions, and values whether it is German, American, or Mongolian and have an awareness of cultural differences. The focus should be placed on adapting feedback to concrete needs, resources, and capacities of the feedback receivers. Based on our experiences and discussions, we propose to gradually introduce and implement constructive feedback in these types of social environments by continuously scaffolding and successively deepening the intensity of feedback from day to day as follows in a one-week project course.

- On Monday, the teacher or team adviser should introduce the concept of the feedback approach on a meta-level and reflect upon and mediate unusual aspects with students along with introducing the rules of giving and receiving feedback. This should be followed by a demonstration of valuable resource-orientated feedback. Therefore, the team adviser might, at first, give solely positive reinforcements as feedback and exclusively at the team level (e.g. use of adequate working techniques applied by the team or collective team behaviors that could be seen as resources for effective teamwork). Thus, at the end of the day, students should have an idea of and the rules of feedback, and further be enabled to experience the reinforcing effect of receiving positive resource-oriented feedback.
- On Tuesday, the teacher or team adviser may repeat the philosophy and rules of constructive feedback while demonstrating the method themselves. Additionally, they should guide and encourage the students in groups of two to reflect upon their collaboration with the following questions: “Which techniques and team behaviors were supportive for teamwork and therefore should reinforced? What further ideas do you have to continuously improve your common teamwork?” It is suggested to use anonymous or semi-anonymous tools for this exercise. After collecting the responses, the team adviser should moderate a discussion over the named aspects and conclude

with additional regulating and resource-orientated feedback, including positive and negative aspects along with suggestions for improvement, and all should be supported with reasoning. The team adviser could also moderate a discussion with students about their experience with the feedback method.

- During the following days, the procedure should be continued with a successive increase in encouraging the students to expressing feedback to their own teamwork. Therefore, it depends on the students if the procedure should be more a partnership or use more (semi-) anonymous techniques. The aim of the scaffolding development should be to empower students to give feedback in a constructive, individual, and openly expressed way.
- Friday could end with a review and reflection on the entire week, guided by the team adviser. To aid understanding and to arrange feedback in a more tangible way for students, the procedure can be visualized each on a flipchart or on cards.

With this adapted approach of successively giving and receiving feedback in team advising, the procedure can be managed in a less direct way, and therefore, might be more accepted in social and cultural environments where participants are not used to this style of feedback. A focus on consequent positive reinforcement of team resources and constructive team behaviour is important to pave the way for a common basis of feedback. Further, team advisers need to not only introduce the practice of giving and receiving constructive feedback but also reiterate (many times) the underlying values and highlight the chances for collaboration within the team, learning and improvement, and the potential for personal growth and self-determination.

3.3 Step 3 – Mentoring by German staff

This past year, the Mongolian staff had the opportunity to practice, implement, and begin to adapt the German PPBL model at their university with mentoring from the German staff. Once more, as in the previous two years, a help desk was not utilized due to the small number of students, but expert interviews were with additional Mongolian academic staff participating and consulting on the student project solutions. Mongolian academic staff were the team advisers and introduced the key components of the PPBL model to the student teams with mentoring by the German staff along with technical advising. At the end of every day, a short reflection meeting was held between the Mongolian and German staff to discuss challenges and successes of that day and exchange ideas and thoughts for the next day. Overall, the project was run smoothly with good solutions presented by the student teams at the end of the project.

Additional informal reflection and discussion may be needed to help fully transition and transfer the model as challenges may arise in training new staff and involving upperclassman who took the project course as first year students.

4 LESSONS LEARNED, CHALLENGES, & RECOMMENDATIONS

Through this intercultural knowledge transfer of a PPBL model, we have learned to begin adapting the German PPBL model to a Mongolian university in collaboration between the German and Mongolian academic staff. Together, we have learned it is better to have more active technical advisers in teams and to have a modified feedback approach by team advisers. In consequence, this should empower the Mongolian university and staff to make the projects their own including materials and resources. Additionally, communication of different working styles at the beginning sets a basis for showing opportunities of possible adaptations of the concepts.

Challenges still remain in fully transferring and adapting the PPBL model. The major one is further training of team and technical advisers along with support staff to help run and organize the project courses and be self-sufficient.

From our experiences in an intercultural knowledge transfer, we recommend keeping the core part of the model similar between developed models but adapting as needed to be culture-specific such as the adapted, scaled, smooth fading-in practice of reflection and feedback. Developing local, “authentic problems” tasks that directly impact students is an easier way to get students excited and motivated about a project and for a university to adapt the model. For these knowledge transfers to successfully occur and for a new university to adapt and improve the model, there needs to be commitment and buy in from all stakeholders, including students, academic staff, and administration, by participation but minimally support these types of PPBL models. Any new adaptions to a system need time to be fully implemented; therefore, the adapted PPBL model will also need more time to show its full strengths.

Through critical reflection on our own practice in transferring the developed PPBL model, there is a need for further evaluation. We recommend collecting data and evaluating it (with appropriate permissions) to further quantify the quality and effectiveness of the adapted model along with identifying areas of improvement. It is also important to have future evaluations in the students’ mother tongue to reduce validity concerns over a potential language barrier.

In summary, international exchanges like these enables us to continuously improve and readjust the international and interdisciplinary PPBL model for culture-sensitive aspects, meaning not just handing over and teaching our PPBL model and tools to adapt it but also learning from our international colleagues and improving our project courses from this new knowledge we gain. Today’s needs for these types of transfers include eliciting formal organizational knowledge and tools and informal, more personal knowledge and experiences.

Minor in sustainable design for engineering design education. Experience at UPC Barcelona Tech

J Segalas
Director
Research Institute for Sustainability Science and Technology , Universitat Politècnica de Catalunya – Barcelona Tech
Barcelona, Spain
E-mail: Jordi.segalas@upc.edu

ABSTRACT

Sustainability and Internationalization are key factors within educational programmes and institutions nowadays. Offering programmes that focus on these factors at undergraduate level has been a priority at the School of Engineering of Vilanova i la Geltrú (EPSEVG), Barcelona, and since 2012, it has run the International Design Project Semester (IDPS) Erasmus mobility programme.

IDPS trains engineering design students by applying Project Based Learning in intercultural groups. The working language is English and the programme is designed for bachelor degree students in their 7th or 8th semester. The IDPS programme offered at the EPSEVG emphasises the introduction of competences in sustainability and human technology.

The main objective of the IDPS is to improve the learning outcomes and competences of industrial design engineering students especially in areas of Design for sustainability. It is divided into two parts. One part covers four (3 ECTS) credit core courses in specialist fields of study such as Eco Design strategies, Human Centred Design , Sustainable Design and Business Practicum, and the second part involves working on a project (18 ECTS). Additional seminars and workshops compliment the courses and vary from programme to programme. Local design companies and research groups propose the projects.

Since 2012, 43 students from 11 nationalities has participated in the IDPS working in nine real projects. This paper shows the design methodology used in the IDPS programme, its structure, the sustainability competences achieved by the students and the lessons learnt during the 5 years of the program.

Conference Key Areas: Sustainability and Engineering Education, Engineering Skills

INTRODUCTION

Since 1991, the Universitat Politecnica de Catalunya (UPC) has focused on introducing Sustainability education in all its engineering and architectural programs through two environmental plans (1996-2000, 2000-2005), and currently through the UPC Sustainable 2015 [1] plan.

In 2009 UPC has introduced engineering design of product development degrees education at Bachelor level and in 2017 it is starting its first master degree in design. Due to its experience in embedding sustainability in the engineering degrees, when designing all this degrees sustainability has been at the core of the competences to be acquired by students.

Next sections will present the experience at undergraduate education where a minor in Sustainable Design, International Design Project Semester, at the School of Engineering of Vilanova I la Geltrú (EPSEVG) has been run since.

1 INTERNATIONAL DESIGN PROJECT SEMESTER

The International Design Project Semester (IDPS) is a 30 ECTS minor offered at Engineering Design and Design students that are finishing their undergraduate studies. Learning outcomes

1.1 Minor structure

The IDPS is a unique program in this respect and is totally adapted to the European Higher Education Area and is suited to Bachelor Design Engineering students in their final study semester. In brief, the program has the following characteristics:

- It is international and multicultural;
- It is for Industrial Design Engineering students
- English is the working language;
- It addresses the real needs of companies;
- It is an intensive, one-semester program;
- It is worth 30 ECTS credits;
- It works out the Sustainability competences.
- It combines both face to face and distance teaching methods (blended learning).

The IDPS has three complementary parts:

Part one: A project (18 ECTS): During the semester and under the guidance of an academic tutor, an international team of four to six students works on a real-life project for a Spanish for an international company. The teams are made up of students from an Industrial Design Engineering background from Europe and beyond. Individual and group tutorials are offered during the semester.

Part two: Core courses (12 ECTS): Four courses are offered, Eco-Design, Human Centred Design, Sustainable Value Design and a fourth course which varies from year to year to adapt to the demands and profiles of each program. Students are awarded 3 ECTS for each of them.

Part three: Seminars: short intensive practical workshops on topics related to sustainability, advertising, product system services etc. are also offered to broaden the students' vision on sustainability and to enhance the work related to the project. These complementary workshops also help students develop their communication and cooperation skills.

The projects are real-life projects proposed by companies. The project proposals from the companies must meet the following criteria:

- Sustainable in focus:
- Complexity: final year Bachelor students should be able to carry out the project.
- Difficulty: the project can be completed in 15 weeks.

- Supervisor: the company has to provide a supervisor and facilitate all the information needed to carry out the project in English.

The IDPS structure and agenda is illustrated below (Figure 1). The program lasts 15 weeks and the final week, week 16, is given over to evaluations, examinations and oral presentations: students deliver their assignments for the courses, submit their final report –scientific paper- and a poster on the project and present their conclusions orally in front of a scientific evaluation committee.

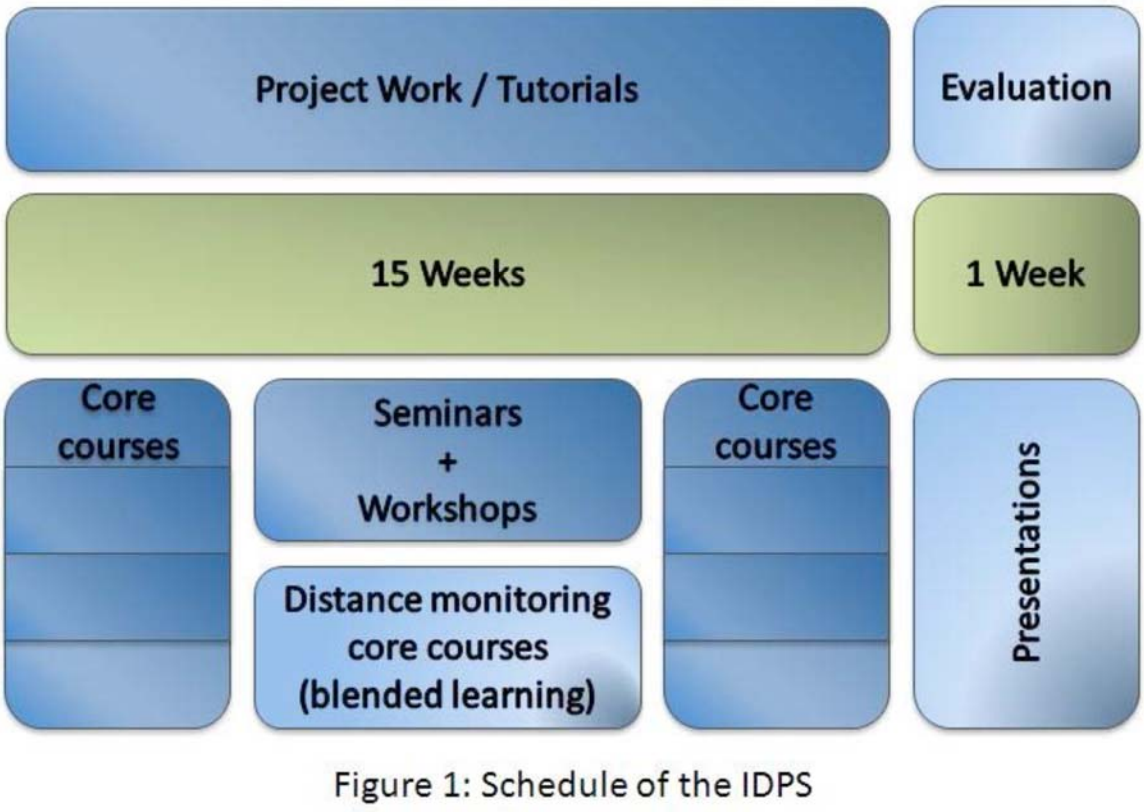

Fig. 1. Blended learning Schedule structure of IDPS

Project work begins when the program starts and lasts its entire length. The courses are split into two main blocks; one at the beginning and the other towards the end of the program. The interim period allows students time to continue developing the project, attend the additional workshops and seminars and interact with the course teachers using virtual platforms such as the digital campus, Skype, Wikis etc.

To make the project recognized for students, learning portfolio Erasmus mobility agreements are signed between universities with design degrees.

1.2 Projects

The projects are proposed by companies and are "modulated" by faculty in order to assure that project fit learning outcomes and competences of students involved.

Table shows a typical description of a project once it has been approved to be run at the IPDS program

Table 1.Exemple of Project description

Project
Title: (Title and pictures related to the project) Paediatric and neonatal lung simulator 
Introduction: (Explain the framework of the project and the problem to be solved) The objective is to design a neonatal/paediatric lung simulator. These devices are useful both for research and educational purposes. Nowadays there exists a wide variety of them from very simple ones, even homemade with garden connectors to very sophisticated ones like SIMVENT. Former lung simulators are designed for research studies in order to check ventilator capabilities. On the other hand, simple lung simulators are used basically for educational purposes; they are cheap and even easily constructed. Unfortunately, these simulators are not very precise or reliable to create standard clinical scenarios, so the professor sometimes faces simulation problems during hands-on sessions.
Project Brief: (Describe the project specifying the main objective and its outcomes, design specifications, etc…) Design a lung simulator for educational purposes able to create standard clinical situations like decrease of compliance, increase of resistance or leaks in neonatal and paediatric scenarios. The lung simulator has the following different parts: - Design of the mechanical device transportable in a small suitcase. Two sizes of lungs available. Neonatal (25-50 ml) and paediatric lungs (125-250ml) - Internal mechanism (resistance, etc) to generate pre-defined common clinical scenarios with several degrees of severity A concept prototype of the device has already been developed by students of the precedent IDPS. The challenge is to continue developing the project so as to deliver, test and validate a fully operational prototype that could eventually be used in a real-field environment. To meet this challenge, performance by the prototype should allow for: - Connection to different sizes of lungs - Generation of changes in compliance and resistance - Remote wireless operation by the instructor through an application running on a mobile device (smart phone or tablet) - Testing and validation in a real-field simulation environment

1.3 Six years' experience results

The IDPS program started in 2012, and we are now running its 6th edition. During the five years of the program 48 engineering design students from 12 nationalities have participated in the program (Figure 2), ensuring the internationality and inter-cultural learning of the program. Students have worked in 15 real projects related to all kind of sectors: ICT, furniture, robotics, domestic appliances, industrial machinery, buoys for marine industry, etc. (http://www.epsevg.upc.edu/idps/idps-course/projects-from-previous-idps-programmes)

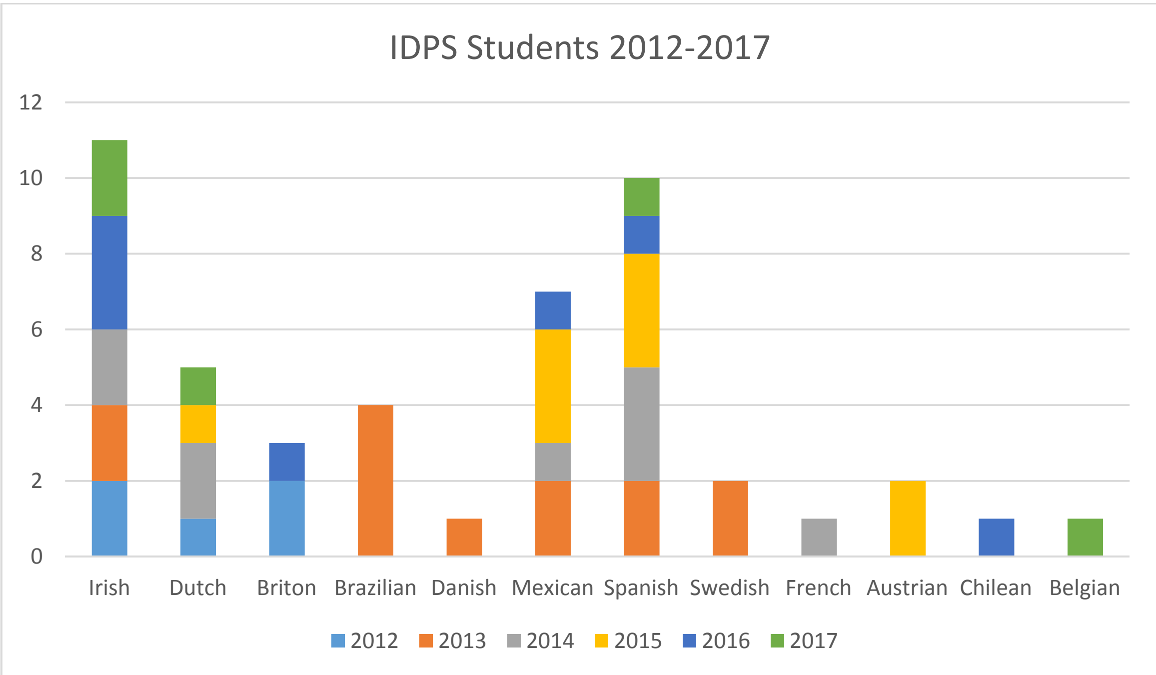

Fig. 2. Students participating in the IPDS program

Participating students were asked to complete questionnaires to provide the EPSEVG with feedback on the course and to show where improvements could be made. The questionnaire used is the Students' Evaluations of Educational Quality (SEEQ) questionnaire [2]. It measures nine distinct components of teaching effectiveness that have been identified in both student ratings and faculty self-evaluations of their own teaching. Figure 3 illustrates the results from these questionnaires, where we can see the high level of satisfaction of student for all courses.

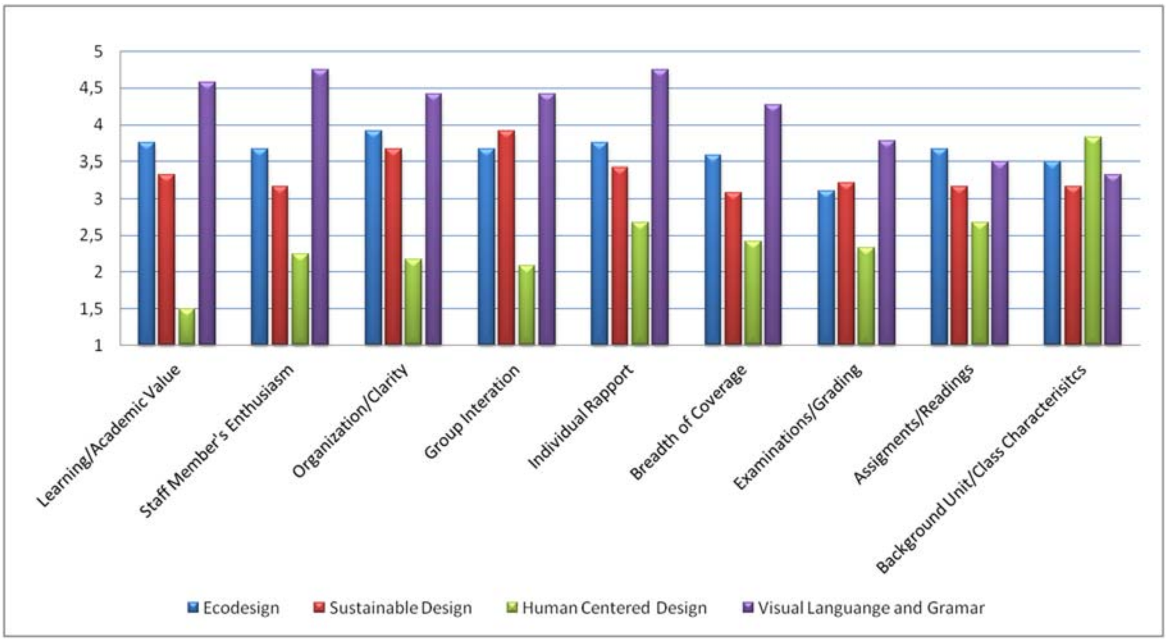

Fig. 3. SEEQ Courses evaluation by students

2 CONCLUSIONS

This paper has introduced an undergraduate example of engineering design for sustainability at UPC Barcelona Tech. The experience show a minor (30 ETCS) for final year Engineering Design students at bachelor level.

The author highlights that using community oriented and constructive learning approaches [3], where students work most of the time in real projects proposed by companies is crucial for sustainability education in general and specially in Sustainable Design education.

3 ACKNOWLEDGMENTS

I would like to thank the students, faculty and stakeholders that have participated in our experience.

ABSTRACT

Energy storage systems are vital for success of electric mobility. Thus, knowledge of energy storage systems behaviours is essential for the development of electric vehicles. Universities and vocational training institutions are urgently required to educate specialists in electrical storage systems. A safe and easy-manageable battery test system was developed to improve the outcomes of student learning of battery storage systems and to allow practice for future employment through hands-on laboratory training. This test system supports temperature-dependent experiments with different cell types including lithium-ion cells, and incorporates a redundant safety shut-off module that protects students from being injured. Based on this system, a new energy storage laboratory course was developed. This course covers four main content areas of battery energy storage: (1) contact & isolation resistance, (2) open-circuit voltage, (3) internal resistance & power, and (4) energy of cells. This new laboratory course was introduced in summer 2016 and has already been conducted with several full-time and part-time student groups.

INTRODUCTION

Transportation currently experiences a major period of change that is focused on minimizing the environmental impact associated with motor vehicles. Battery-powered electric vehicles play an important role in development of greener cars that minimize pollution in big cities. One of the central challenges for the design of these vehicles is the efficient storage and provision of power and energy by an energy storage system on board. As such, academic qualification in this area is essential for the mid- to long-term success of electric mobility [1]. Highly trained professionals are needed and universities as well as vocational training institutions have to find ways to meet this industry demand [2]. Thus, teaching modules on electrical energy storage systems are increasingly incorporated into existing and new study programs related to electric mobility. It has been reported that when practical training complements theoretical lectures, it significantly improves the outcomes of student learning [3]. In addition, laboratories provide valuable hands-on practice for future employment [4].

1 BATTERY TRAINING

The Technische Hochschule Ingolstadt (THI) offers a wide range of qualification programs in the field of electric mobility. Students may choose between various full-time and part-time bachelor and master degree programs, which include lectures on electrochemical energy storage systems. With a profile of a University of Applied Sciences, the consolidation of theoretical knowledge by means of practical experiments in the teaching laboratory is of particular importance for all of these study programs [5].

To prepare graduates for fieldwork with electrochemical cells, a new energy storage laboratory has been developed, which must meet conflicting framework conditions. On the one hand, laboratory space, financial resources, and the students' time are limited while on the other hand, science about electrochemical cells is a growing and rapidly evolving field, which gets increasingly complex to teach. Therefore it was decided to reduce the new laboratory to the most relevant knowledge of battery systems. Students should strengthen their basic understanding of electrochemical storage systems and learn about the practical behaviour of battery cells – building up universal knowledge for their future career. The focus was laid on practical knowledge of the most important parameters of battery cells. Students should be able to determine these parameters self-sufficiently by means of appropriate experimental setups – competencies that are necessary to design energy storage systems.

The identified learning objectives were grouped into four main content areas: (1) contact & isolation resistance, (2) open-circuit voltage, (3) internal resistance & power, and (4) energy & efficiency.

These content areas are taught during five discrete laboratory sessions, three hours in duration each. These laboratory sessions lead to a workshop in which the individual students' measurements are used to parameterize a simulation model and to design an energy storage system in Matlab/Simulink.

The initial plan to conduct a set of laboratory experiments on battery storage led to the specifications of the battery test system for such laboratories. Unfortunately, no fitting equipment, which would allow execution of the planned experiments within the abovementioned framework conditions could be found on the market. Ready-to-use industrial battery cell test benches and temperature cabinets are generally large, multichannel, and expensive devices, which are impractical for laboratory work in small learning groups. Thus, a small and flexible cell test system was developed, which allows safe and effective individual learning experiences for the students. The development was funded by the German Federal Government's Showcase Program “Academic Education Initiative on Electromobility”. The developed benchtop test system supports temperature-dependent experiments with lithium-ion cells and other types of energy storage cells, while a safety shut-off module ensures a high degree of safety during operation at all times. The combination of all functions required for an energy storage laboratory in a compact design is a unique feature of this test system.

Funding by the Faculty of Electrical Engineering and Computer Science allowed a complete teaching laboratory at THI to be equipped with 13 battery test systems. The hardware and the newly created laboratory experiments were tested in various study programs on electric mobility [6]. The students have evaluated practical experiments that utilized the new system more favourably then similar experiments conducted using computer simulations [7].

2 BATTERY TEST SYSTEM

The battery test system is based on a 19-inch table top case of three rack unit height. Its housing consists of three modules with standardized plug-in technology according to IEC 60297-3-101, and allows simple adaptation of the test system to the desired functional range or future developments through connectors according to IEC 60603-2.

The functions of the three modules that are shown in *Fig. 1* and *Fig. 2* cover all needs of the energy storage laboratory. Included are a potentiostat/galvanostat module for cell measuring operations, a thermostat module, and a safety module.

Fig. 1. Battery test system for hands-on laboratories. Students strengthen their basic understanding of electrochemical storage and learn about the behaviour of cells.

As even the production of the tester was used to educate students, the circuit boards were designed by the researcher in a way to enable easy manual assembly by student assistants in a separate project. Thus, most components are in the relatively large SMD format 0805. An ARM Cortex M4 processor was used as an arithmetic unit in all modules. The housing including all submodules and integrated power supply unit weighs 11.5 kg.

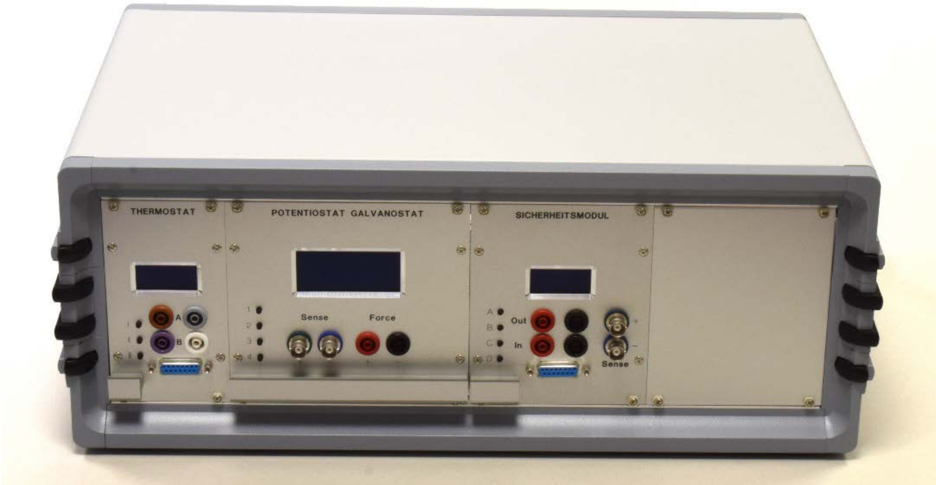

Fig. 2. Battery Test System, from left to right: thermostat, potentiostat/galvanostat, safety switch off module

2.1 Potentiostat/Galvanostat

The central element of the tester is a potentiostat/galvanostat. It allows to conduct experiments with small single cells with amp-hour capacity up to 600 mAh. Currents and voltages can be applied to the cell and may be measured time discrete. The voltage range is symmetrical for measurements up to ±12 V, with currents up to 8 A for discharging and 4 A for charging. In addition to the DC component, an AC voltage of lower amplitude can be overlaid for impedance measurements. In this case, the device determines the impedance's magnitude for frequencies up to 10 kHz and its phase for frequencies up to 5 kHz. The new test system offers a continuous frequency range with 1 Hz resolution.

Apart from technical implementation, finding a good compromise between cost/production efforts and measuring accuracy was challenging. A test system should be easy to build and to maintain, and at the same time should be accurate enough to provide a realistic test environment for the students. Therefore, focus was laid on optimized measuring accuracy and not on the exact analogous injection of current and voltage. If the system injects inaccurately, the resulting errors will automatically be corrected by the measured data (*Fig. 3*). For voltage measurements the error is below 10 mV, for current measurements the error stays below 5 mA in the specified temperature range (21 °C ±5 °C). The down sampled data rate for the time discrete transfer to the computer is adjusted automatically in the range between 312 Hz and 625 Hz.

The galvanostat/potentiostat is controlled from a laboratory computer via serial communication (USB) using C# and Java-based control programs as well as a LabVIEW driver. The Java program was used for the student laboratory, because it is similar to software used for industrial test equipment regarding architecture and user interface. The program was developed during a master's thesis and allows learners to freely program the steps and control structures to implement a certain experiment. Conformity to industrial test benches prepares the students for their later professional life.

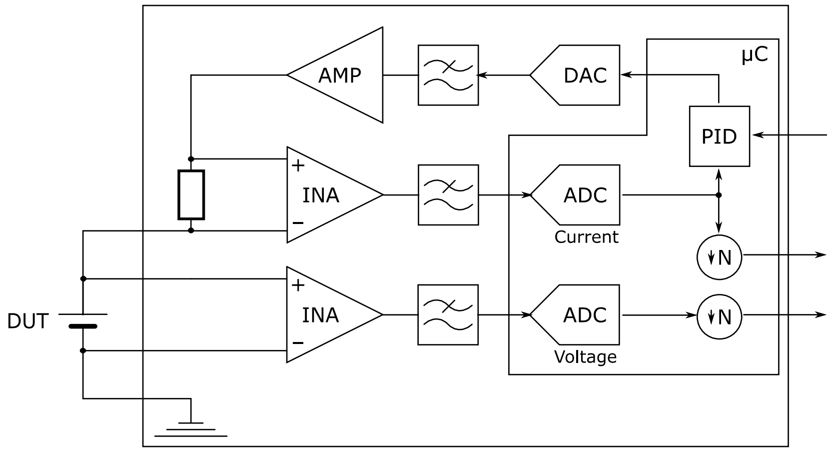

Fig. 3. Simplified working principle of the galvanostat. Actual current and voltage are converted to digital values using two synchronized ADCs. After downsampling the values are submitted to the controlling computer. The current is compared with the target current by software and controls the DAC.

2.2 Thermostat

A major challenge for electric mobility is the strong temperature dependence of parameters of electrochemical energy storage systems [8]. Thus, it is important that students can comprehend the effects of high and low temperatures on the performance of battery cells. Unfortunately, this cannot be achieved using industrial temperature cabinets, which are optimized for testing larger test objects. These cabinets are too big in size, expensive and don't allow changing temperature of small single cells quickly enough to conduct a laboratory within two to three hours.

Besides the requirements on the equipment, the waiting time for a homogenous temperature distribution within the cells must be considered for the lesson preparation. To be able to carry out various temperature-dependent measurements during a lesson, especially the cooling performance is essential. For example, to conduct several tests on the internal resistance of a cell according to ISO 12405-1 within a teaching unit of three hours, cooling from room temperature to -18 °C was required within 20 minutes.

To avoid the disadvantages of convection cooling or fluid thermostats and to solve the problem of minimal time, a small, cost-effective, and rapidly responding two-stage thermoelectric cooler as shown in *Fig. 4* was integrated into the battery test system. Cooling and heating are based on Peltier elements, which allow temperature control in a range from -25 °C to 50 °C. To achieve rapid cooling (*Fig. 5*), the test cell is in direct contact with the metal on four sides. The chamber is made for cells with maximum dimensions 90 mm x 34 mm x 30 mm. The cooling stages are driven by two modulated H-Bridges, providing up to 250 W of power. Heat flux losses are reduced by a foam cube, which isolates the cooling device from the environment. The chamber temperature is measured with an absolute error below 1 K. This external cooling system weighs 5.0 kg, its dimensions (26 cm x 26 cm x 20 cm) allow for easy storage while not in use.

The thermostat supports remote control, utilizing the galvanostat/potentiostat module as mediator between the USB-communication and the CAN-based bus between all the modules.

Fig. 4. External heating and cooling system

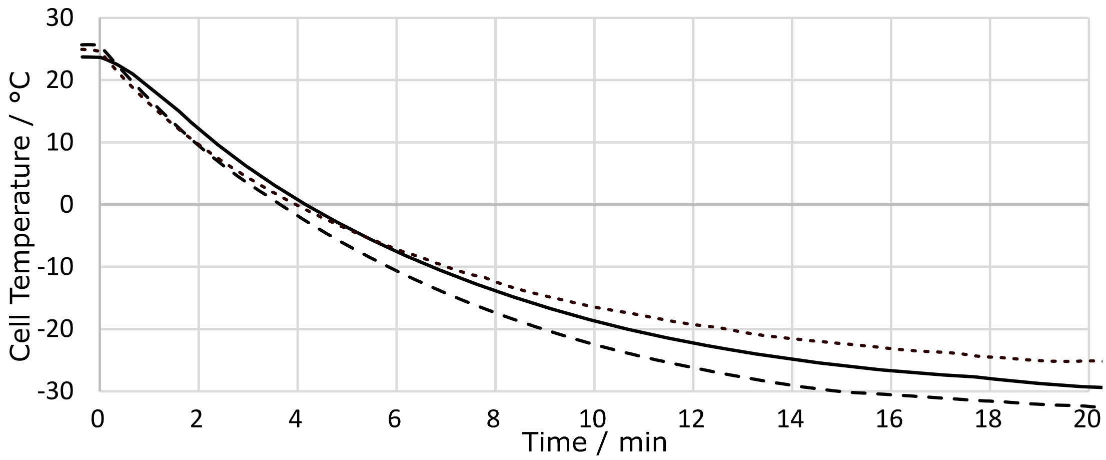

Fig. 5. Max. cooling performance of three exemplary external heating/cooling systems, T_{env}=25 °C

2.3 Safety switch off module

Lithium-ion battery cells are potentially dangerous. In case of mistreatment, they may burst or burn [8]. To ensure the safety of the students at all times, experiments must be either greatly simplified or prepared in step-by-step instructions, which the student has to follow without any degree of freedom. However, this style of instructions would preclude students from gaining skills of planning their experimental work, the skill that is at the core of the engineering profession.

To enable students gaining skills in planning experimental work, a special safety shut-off module is integrated into the test system. This shut-off module is pre-parameterized by the instructor and allows the students full autonomy in controlling the battery system, and minimizes the need for supervision. The module monitors three parameters of the test specimen: (i) current (±12 A), (ii) voltage (±12 V), and (iii) temperature. If the ranges of these parameters fell outside of the range permitted by the instructor, the module automatically disconnects the cell from the test system. It is important to note that the switch-off value may be configured to be pulse-length dependent, as most battery cells allow pulses outside the cell's specified range for a short time. Since this safety shut-off module can neither be influenced intentionally nor unintentionally by a student, he has full freedom to program the potentiostat/galvanostat and may gain valuable learning experience through trial and error.

3 EXPERIMENTS

The developed test instructions are not given in a step by step style. Through decision-making freedom, instructions encourage reflection on the new topic in an environment that stimulates hands-on learning from experimental errors.

The following student experiments have been tested and improved iteratively since summer 2016: (1) Charging/discharging of different individual accumulator cells to measure the cell voltage as a function of the state of charge, (2) Determination of the internal resistance according to ISO 12405-1, (3) Determination of maximum achievable power dependent upon temperature, (4) Capacity determination dependent upon the load profile, (5) Measurements under a load profile in order to parametrize a Matlab/Simulink model, (6) Determination of energy efficiency under various conditions. All laboratory instructions were written to encourage learning through trial and error. They were specifically tailored to support theoretical knowledge acquired from the accompanying theory-based lecture. The biggest challenge while creating the experiments was the limited time for a single student's laboratory (e.g. to cool a specimen down, discharge, charge a cell, and to wait for stable states is extremely time consuming). It was often necessary to divide the students into subgroups, who obtained differently parametrized experiments (e.g. discharge rate) and to let them consider the collected data from all groups for evaluation. The laboratory was piloted in summer 2016 and repeated with improvements in 2017.

The aforementioned experiments are a selection for the study programs at THI. Ideas for additional experiments using the battery test system are: (1) Observing the behavior of cells under load in driving cycles, (2) Development of SoC/SoH determination methods, (3) Impedance spectroscopy, (4) Use of two lithium cells in series connection to demonstrate experiments using battery management systems.

4 CONCLUSIONS AND RECOMMENDATIONS

The described battery test system allows students to easily conduct hands-on experiments in an energy storage laboratory. The students can carry out practical experiments on accumulator cells in a safe, flexible learning environment. Current focus lays on repeated evaluations of the practical training with different groups and types of students for stepwise improvements. The newly developed laboratory sessions and devices may give other educators a good starting point for battery laboratories. In addition to practical training at universities, the developed practical experiments and equipment can be used at other educational institutions as well as by training departments of industrial corporations. More than sixty percent of young people in Germany take part in the dual system of vocational training [9]. Practice-orientated vocational schools, technical colleges, or colleges for master craftspeople may use the hardware in combination with adjusted teaching material.

5 ACKNOWLEDGMENTS

The authors wish to thank the laboratory engineer Sönke Barra for his assistance while planning, preparing, and conducting the experiments. Also to Christoph Nebl and the student workers who helped to produce the devices. The Federal Ministry of Education and Research provided funding for the project "Academic Education Initiative for E-

Mobility Bavaria – Saxony" which was used for the development of the prototypes of the devices. The devices used in the laboratory were built from finance of the Faculty of Electrical Engineering and Computer Science at THI.

ABSTRACT

In this system paper we will present a learning experiment - a unique three-day global product design relay marathon organized by the Design Factory Global Network (DFGN). The experiment called Rat Relay simulates a real-world situation in product development where very often a person or team is only working on a project for a limited time and not from beginning to end, individuals work in multidisciplinary and multicultural teams around complex problems, and everything is done with a fast pace. Rat Relay is a learning experiment developed by the Design Factory Global Network, a network of innovation hubs in universities and research organizations in five continents of the world aiming to contribute to transformation of learning and research through a passion-based culture of interdisciplinary collaboration and effective problem solving.

INTRODUCTION

In this paper we present the process and experiences gathered during the first official global product design relay marathon in the Design Factory Global Network, previously piloted in 2016 with four international hubs. The aim of this paper is to share learning outcomes and results of the exercise, and to further develop the approach for collaborative learning for the next round of Rat Relay.

1 THE SETTING

1.1 The concept of the experiment

The Rat Relay is focusing on finding novel ways to teaching product and service design in a global context and in distributed teams. The number of participating institutions is not limited or fixed. However, in this paper we will present how the experiment looked like with six participating institutions. The Rat Relay is an experiment about real-time global collaboration, and at the same time a local learning project where each institution offers for a local team a learning environment where the learning and working can take place. Further on, the institution representatives together with a company, start-up or NGO prepare a global, real-life challenge, and gather students to participate in teams of ca. five people, and invite teaching staff to act as coaches for the students.

This teaching and learning experiment is divided in six slots of six hours each, to complete a 36 hours' marathon in three days. Each slot represents a different phase of a design project. Each institution participating in the Rat Relay launches off their challenge during the first slot to their local team, which works on the given challenge for the first six hours. The challenge will then be passed on to a new country, just like runners pass on a baton in a relay, where a new interdisciplinary team works on the challenge in a next phase of the project for another six hours. In the end the challenges return back to the originating country for finalization of the outcomes. Table 1 presents an example of the schedule from Aalto Design Factory.

The six slots are distributed to three consecutive days, to morning and evening shifts by taking advantage of time zones to make a real-time relay between Europe and South America in this particular case. The distribution of the shifts in each location, according to the time zones, can be seen in Figure 1. In this experiment the teams did not work around the clock as the shifts took place only on mornings and evenings in each country. Besides, in Figure 2 there is the distribution of the teams of the Rat Relay 2017 and the sequence of the projects going from one institution to another one; in this Figure 2, the meaning for the letters in the right- and leftmost columns are: "n" goes for "night", "m" goes for morning and "e" goes for evening. The far most left column represents European and right side South American time zones. The participating teams of 2017 are denoted as FIN (Finland), NED (Netherlands), POR (Portugal), SAN (Santiago, Chile), CAL (Cali, Colombia), BOG (Bogotá, Colombia).

Fig. 2. Projects sequence among the six participating institutions

Altogether this resulted into 216 hours (i.e. six locations times 36 hours) of project-based learning in globally distributed teams. The Rat Relay experiment took place in April 2017 in Design Factory learning platforms in six different universities: Aalto University in Finland (ADF), NHL University of Applied Sciences in Netherlands (FDF), Porto Polytechnic in Portugal (PDF), Duoc UC in Chile (DDF), and in Pontificia Universidad Javeriana in Colombia in two different cities Bogotá and Cali (DFJ).

	DAY 1 / Wed 26 April	DAY 2 / Thu 27 April	DAY 3 / Fri 28 April
Morning slot 8:00 - 14:00	**SLOT 1** - Project owner: ADF - Brief: International Trade Centre - Send to: DDF	**SLOT 3** - Project owner: FDF - Brief: Red Cross - Comes from: DFJ Cali - Send to: DDF	**SLOT 5** - Project owner: PDF - Brief: The city of Porto - Comes from: DFJ Cali - Send to: PDF
Evening slot 15:00 - 21:00	**SLOT 2** - Project owner: DFJ Bogota - Brief: Intellectus Centro de Memoria y Cognicion - Comes from: DFJ Bogota - Send to: DFJ Cali	**SLOT 4** - Project owner: DDF - Brief: Liberty Sequros - Comes from: DFJ Bogota - Send to: DFJ Cali	**SLOT 6** - Project owner: ADF - Brief: International Trade Centre - Comes from: FDF

1.2. Learning objectives

For students, the main learning outcome of the Rat Relay is to understand the necessity of work distribution in design or product development projects in a real global context. The idea is that only clear and constructive communication about the work done in one phase by one team will enable the best possible progress for the next teams in the relay. In addition, the students get to handle time pressure, improve and increase their argumentation skills for decisions they have made, and learn to document their projects via videos, illustrations, presentations, and photos. Learning outcomes also include process planning, product development skills, teamwork skills, and application of design thinking process. The success of the exercise is assessed with the feedback that is gathered from the teams after each slot, and from the organization providing the challenge after the final results are presented to them.

In the same way, students are able to improve their conflict management skills when different situations take them out of their comfort zones. Students get to work with other students from different countries, disciplines, and languages, thus offering them an opportunity to gain practical information about different societies and communities. In this particular case, none of the participants was an English-speaking country. However, the official language of the Rat Relay was still English, which represented both a challenge and an opportunity for practicing and learning communication skills.

For faculty members or Design Factory representatives, in addition to the valuable experience of coaching the different phases of the project, there are many learning outcomes from the interactions between participating institutions. Essentially the rather short time window pushed participants and coaches to work in non-traditional ways finding ways to communicate ideas to next teams in the relay.

1.3. Six phases and slots

The Rat Relay process was roughly built on six phases of product design, each one developed in a six-hours slot.

- 1st slot: understanding the brief, background research & identifying the user.
- 2nd slot: problem definition & benchmarking.

- 3rd slot: diverging & ideation.
- 4th slot: converging, concept definition & prototyping.
- 5th slot: refining the concept, iterating the prototype & testing with users.
- 6th slot: final prototyping & presentation.

However, following the Design Factory approach to product development, the design processes are not linear and the emphasis is made on the problem or need rather than on the process itself. In that sense, the Rat Relay teams were encouraged to jump across phases if the logic of the problem demanded it. This iteration is central in concept level development projects (Ulrich & Eppinger, 2016), in the Design Thinking approach (Brown, 2008) and in the TRIZ approach (Cavallucci, 2002).

1.4 Grand challenges to be solved

All challenges in the Rat Relay had both a global aspect and a social benefit involved. The idea of the Triangle of Sustainability (Serageldin, 1995)—where all three aspects, economic, ecological and social need to be taken into account—was a key for both the organization of the Rat Relay and the development of the six different solutions to the challenges.

Firstly, the economic aspect was addressed by a symbolic fee for profit organizations participating from the Rat Relay and the fact that all the solutions needed to provide some level of market validation. Secondly, the ecological aspect was addressed in a way of work where the teams gained large global perspective to societal challenges and problems without the need to physical travel around the world thus reducing the carbon footprint related to transportation of the projects. Finally, the social aspect was addressed with the selection of the challenges, the alliance with organizations with a social conscience and the forming of diverse teams where every background and context was there to enrich the general capabilities of each local team.

In the Rat Relay experiment the six challenges were provided by the International Trade Centre based in Geneva, Liberty Seguros (insurance company in Chile), San Ignacio Hospital Memory and Cognition Center: Intellectus in Bogotá, Colombia, Social Foundation De Menos a Más for vulnerable population in Cali, Colombia, The International Red Cross in the Netherlands, and the City of Porto in Portugal.

The diversity of profiles and academic backgrounds of the participants makes this experiment particularly interesting. Due to the perceived nature of the product development marathon and the participating institutions, it could be more obvious to attract people from engineering, product design and business. However, the call for participants was open also for disciplines "at the border" such as arts, ethics or health sciences, and gathered also many of them to join. We argue that a global challenge will always need diverse points of view to be solved, thus calling for a collaborative environment beyond the boundaries of academic fields.

Table 2 depicts—as an example of the interdisciplinary nature of the Rat Relay—the background of the participants at the Aalto Design Factory in Finland. Of the 22 participants 18 were university students, one visiting scholar, one university faculty member and two junior high school students. The participants also represented 10 different schools and various disciplinary backgrounds. Similar interdisciplinary backgrounds were to be found also in other participating institutions. The majority of the participants in all six locations were BA and MA level students, but also many vocational students, industry professionals, university faculty, and even junior high school students participated the experience.

Table 2. Backgrounds of the participants in Aalto Design Factory, Finland

School	Number of Participants	Discipline
Aalto University of Arts, Design and Architecture	3	Industrial Design, Design, Collaborative and Industrial Design
Aalto University School of Science	2	Technical Physics, Computer Science
Aalto University School of Engineering	6	Production Engineering, Mechanical Engineering (3), Marine Technology, Product Development
Aalto University School of Business	3	International Design Business Management, Marketing, International Business
Aalto University School of Electrical Engineering	2	Microelectronics, Automation and Systems Technology
NHL University of Applied Sciences	1	Design
University of Helsinki	1	Finnish and Nordic History
Metropolia University of Applied Sciences	1	Digital Media
Arcada University of Applied Sciences	1	Media Management
Other	2	Junior High School

In the following sections, we will depict the Rat Relay as a unique learning method for global collaboration, present the data and experiences gathered in April 2017, analyse the process, and address future possibilities of research and next steps.

2. DATA GATHERING AND ANALYSIS

The data about the Rat Relay experiment was gathered through a survey taken by the participants after each time slot and through the reports of organizers in each Design Factory. The survey, which gathered 63 answers, looked into the diversity of the team, the previous design experience of the participants, the decisions made during the six hours' slot, interactions within teams, and the results of each round, accordingly. The intention was to support understanding the participant's attitudes and the dynamics within Rat Relay over the 36 hours' period. The analysis was done in a privacy-preserving and anonymous fashion. Table 3 presents the number of participants and coaches in each institution. The total number of participants in all six institutions was 166 with 30 coaches.

Table 3. Number of participants and coaches in each institution

Institution	DDF	ADF	FDF	DFJ Bogota	DFJ Cali	PDF
Participants in total	43	22	20	21	42	18
Slot 1	8	6	7	13	26	4
Slot 2	6	2	5	8	13	5
Slot 3	12	5	3	8	9	4
Slot 4	5	4	3	6	12	6
Slot 5	5	6	3	8	18	5
Slot 6	7	6	2	10	21	4
Coaches	8	5	3	3	7	4

2.1 Limitations and context

- The sign-up process was not restricted; everyone was able to sign up to the slot they wanted. This caused some unbalance to the teams.
- In some slots students participated only part of the time, however majority of the time the team participated for the whole six-hour slot. In Cali students worked also locally in parallel teams.
- The Rat Relay was a voluntary activity; students were not awarded ECTS credits.
- In Bogotá, the event took place at the Creative Room of the Ático Building, which was shared with other students who were working on their own activities, but were invited to participate mostly in the prototyping and validation slots.

2.2 Analysis of results

In order to support understanding of the Rat Relay experiment and its results we visualized the data gathered in the survey. Figure 3 depicts four core questions from the survey with answers in a five-point Likert scale, “1” being a strong disagreement and “5” meaning a strong agreement with the claim. Most participants (58%) found that their team’s goals were clear and shared by all team members. Interestingly, more participants (46 % compared to 16%) tend to reflect more because of their designerly attitude. Slightly more (40% vs. 21%) of the participants found that design-based approach helps to improve efficiency. However, there was no clear difference between how participants see they attitude helps to use their imagination outside the working environment.

Fig. 3. Answers to four core questions of the survey visualized.

In the survey our aim was to understand also relevant other aspects around these core questions. Figure 4 depicts answers to questions about the attitude of participants towards the society. As we can evidence, substantially more participants reported that their designerly attitude helps in different aspects to serve the society (inclusiveness, innovativeness, hopefulness, reflectiveness).

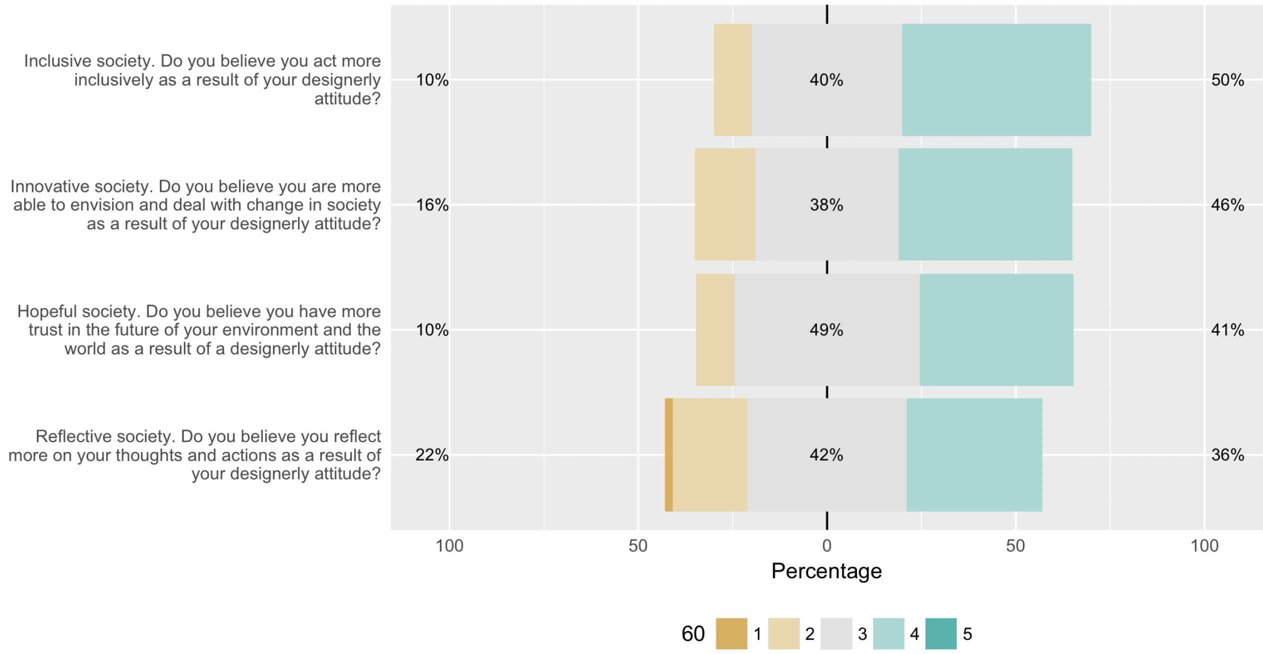

Fig.4. Participants' answers about their designerly attitude for the society.

3. LEARNING OUTCOMES & DISCUSSION

The Rat Relay marathon was organized for the first time with students and real company partners in April 26th to 28th 2017. The feedback gathered from the participants, company partners, and organizing institutions was crucial in analysing the success of the learning experiment and the next steps.

3.1 Student experience

The students reported that they especially enjoyed the intensive nature of the relay marathon to work against the clock and with real time with other Design Factories. They appreciated both the diversity of the teams, and the challenges. The participating students liked the unique approach to work only on a certain part of a project, and thus expected to build on others' ideas, and to send over their progress to the next team in an understandable and compact way. They felt that the communication between the different slots, without any face-to-face communication in between, was the biggest challenge but also the biggest learning experience.

Communication was perceived as one of the big challenges since English language was the main language of the Rat Relay amongst non-native English speakers. To convey ideas and thoughts better, students used drawings, visualizations, pictures, acting, body language, and even music and movie references to enable assertive communication between the slots.

3.2 Sponsor experience

Although the Rat Relay experiment was only a 36 hours' project, all the sponsors received a proper design solution for their challenges, making the six slots division a powerful methodology tool. The phases assigned to each slot were not fixed but worked perfectly as a guide to understand and achieve deliverables for each phase. The NGOs and industry partners providing the real-life challenges were all surprised of the amount of ideas and content students were able to produce in just three days.

Several partners reported afterwards how the Rat Relay was also a great learning experience for them to design and frame their challenges in a better way for student projects. Within the Rat Relay they were able to test an idea and a challenge very quickly and see the end results directly after 36 hours.

4. SUMMARY

In this paper we reported about the Rat Relay experiment, a 36 hours' marathon to provide design-based solutions to a variety of challenges provided by companies, universities and NGOs. We presented the setting, including the idea to have several locations around the world, and how draft designs were passed to following teams in other locations, thus creating a relay effect.

We provided the first analysis and visualization of results of the survey to support understanding the experiment, and also to see how participants think their designerly attitude can help in societal questions. We also presented and discussed the learning outcomes for students. As we evidenced, students found the creative communication between slots without any face-to-face communication to be both most challenging and most supportive for their learning. Organizations that provided the challenge-based tasks for the Rat Relay were both surprised and satisfied about the results.

As a part of the future work we plan to analyse and visualize all the data collected from the survey from this first official Rat Relay experiment. For instance, it will be interesting to look more closely into what influenced students' decisions and whether previous design experience of participants plays a role in the decision-making and final outcomes. The next round of the Rat Relay will take place in the first part of 2018, and we are looking to have more participating institutions, more students, and more coaches, and to use the experiences and results presented in this paper to create an even more engaging setting.

ABSTRACT

The Research Institute for Sustainability Science and Technology under the Master degree in Sustainability Science and Technology organises the course Action Research Workshop on Science and Technology for Sustainability (5 ECTS). The purpose of the course is to put together civil society organisations, local administrations, students and educators to collaboratively undertake responsible research, using transdisciplinary Action-Research methodologies through service learning.

Students work on service learning real projects, related to local sustainability problems, represented by a community entity. Action research methodology is used with a two-cycle approach. After finalising three editions a relevant conclusion is that during the process students faced conflict and frustration situations, within their team and with stakeholders. To face that, an Emotional Intelligence module was introduced in the course and helped students to solve some paralyzing situations. Therefore we suggest that engineering students need specific training in transdisciplinary learning and conflict resolution, otherwise they could collapse in frustration when dealing with real sustainability challenges.

Conference Key Areas: Sustainability and Engineering Education, “I want to contribute to solve local problems”, Engineering Skills

Keywords: Sustainability education, Service Learning, Emotional Intelligence

INTRODUCTION

Sustainability issues are widely recognized as wicked problems [1], which should not be considered as problems to be solved, but as conditions to be governed [2]. There is a general agreement on the need to reform scientific expertise, as it is required to deal with sustainability challenges, by developing new ways of knowledge production and decision-making. In that sense, Stephen Sterling [3] maintains that the nature of sustainability requires a fundamental change of epistemology, and therefore, of education. In relation to engineering education, the Barcelona Declaration [4] highlight the sustainability competences that engineering students should master when graduating.

The Universitat Politècnica de Catalunya (UPC Barcelona Tech), aware of the new sustainability competences that engineers should have, offers a master degree in Sustainability Science and Technology that trains students to become entrepreneurial professionals and agents of change for sustainability. Service learning is one of the pedagogical approaches applied in the master. The following sections explain the learning environment and the challenges and lessons learnt when applying such learning approach.

1 SERVICE LEARNING APROACH

Service-learning is an innovative teaching and learning method with experiential character that integrates service to the community and critical reflection with the academic learning, personal growth and civic responsibility. It is powerful tool for learning and for social transformation, which responds to the ultimate goal of education: to form competent citizens capable of transforming society.

Service-learning is the necessary response to an educational system that is alienated to social needs [5].

There are two main mechanisms that make service-learning an effective educational tool: the process and results. Firstly, it causes a mental process that improves learning. Research shows that complex facts and ideas are best retained when knowledge is linked to Experience [6] and facilitates the transfer of skills and knowledge to real situations [7]. Therefore, when teachers create a reflective learning-service environment, it is likely to improve the understanding and remembering of complex material. Secondly, service-learning produces results of great interest to higher education. Studies show that service-learning contributes to develop critical thinking and problem-solving skills [8] [9], citizen participation, social responsibility and development of values and self-efficacy and self-confidence [8].

Service-learning increases awareness of social justice [10], teaches students to question society from a point of view critical and emphasizes social change rather than charity [11].

Through learning-service, students can develop a vision of the social justice and learn to analyse the issues that are encountered in your life with a critical look at injustices [12].

2 SERVICE LEARNING COURSE

The service learning pedagogical approach is applied in The Action Research Workshop on Sustainability Science and Technologies a course within the Master of Sustainability Science and Technology. It is a 5 ECTS (European Credit transfer System) course, which uses constructive and community oriented learning which has shown to be the most efficient way to train students in sustainability science competences [13], [14].

2.1 Learning outcomes

When finishing the course students will have been trained in the following competences.

- To understand how their work interacts with society and the environment, locally and globally, in order to identify potential challenges, risks and impacts
- To reflect on the results of the service learning process in order to understand the social dynamics that appear when applying engineering approaches in real sustainability challenges

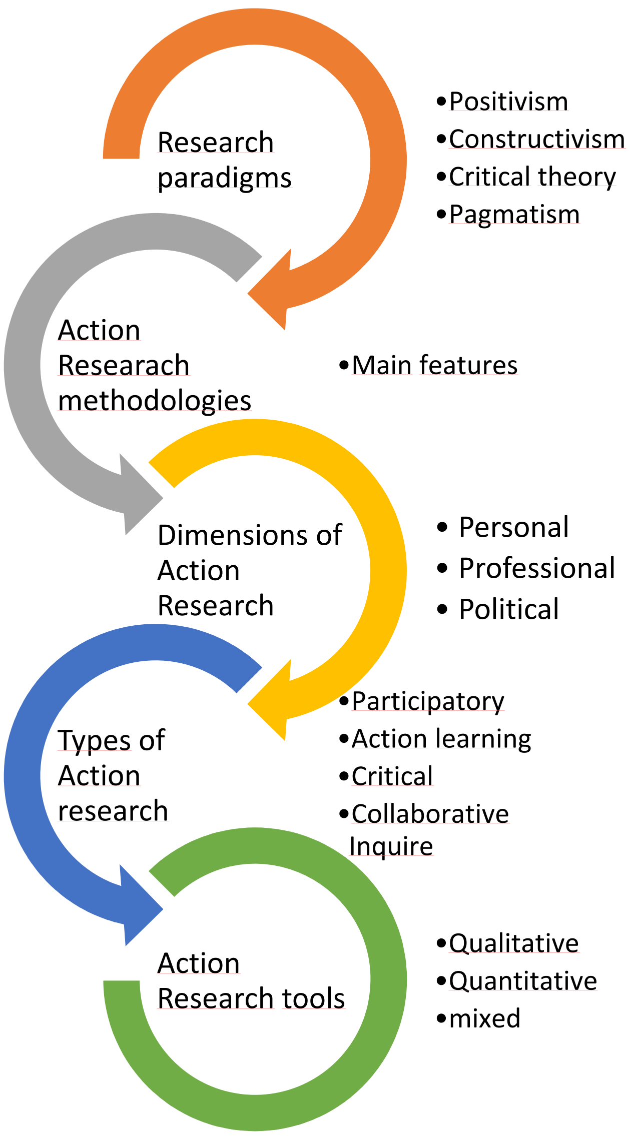

Fig. 1. Action research theoretical framework of the course

2.2 Course structure

The course is organized (Figure 1) around five areas: Research paradigms, Action research methodologies, Dimensions of Action Research, Research tools and Real projects. First students are faced with different research paradigms: Positivism, Constructivism, Critical theory, Pragmatism and their features in order to facilitate their reflection on the research that they may apply in their future work as engineers. Next, students are trained in the main features of Action Research methodologies. Once students are familiar with the main characteristics of action research, they learn about the main types of action research: i) Participatory action research [15]; ii) Action learning [16] [17]; iii) Critical action research [18] and iv) Collaborative inquiry [19]. Students study their main features, pros and cons, methodological approaches and examples. Finally, students are trained in qualitative, quantitative and mixed research tools and methods typically used in action research: Conceptual maps, questionnaires, interviews, backcasting, complexity and network analysis, etc

They apply all their learning in Action Research in real sustainability projects under Service Learning paradigm [20] [21].

3 THE EXPERIENCE AT UPC

The course has been run for three years (2014, 2015 and 2016). We are currently running the 2017 experience. The course is organized around current sustainability relevant topics, broadly related to unsustainability aspects which are analysed in study real-life projects in local real situations, needs or challenges. Table 1 show the general topics for each course, organisations who lead their own real-life projects and the research question for each of them.

Table 1.Service learning projects ran at UPC

Topic	Stakeholder	Real-life projects	Research question
2014			
Sustainable clothing and slow fashion	Clean Clothes Campaign	Spanish fashion in Morocco	What a local clothing company can do to minimize labour exploitation risk, when pushed to find suppliers in Morocco?
	Slow Fashion Spain	A local booming sustainable clothing market	What are barriers and challenges faced by sustainable fashion initiatives in current market?
2015			
Energy poverty in Catalonia	Energy Bank Association BE - Municipalities Premià/Sabadell	Detection of motivations to participate in the BE in Premià	What are the factors that influence the decision to join or not the driver group of BE?
		Phase 1 of implementation of the Energy Bank in Sabadell	What key factors that encouraged real participation in a local energy program can be used for BE?
2016			
Energy poverty in Catalonia	Energy BE – Premià	Phase 2 of BE implementation in Premià: private sector	What affordable and sustainable offer could facilitate the organizations involvement to BE?
Gas Geopolitics	OdG- Debt Observatory in Globalization	MIDCAT, huge construction of a mega- pipeline for gas interconnection France-Spain	What is the capacity of this civil organized campaign facing to maximize transparency and public accountability?
		Gas imports of the Port of Barcelona	What is the city responsibility on the perpetuation of fuel energy model based on natural gas?
UPC's water management teaching	EWB- Engineers Without Borders	What kind of water management is promoted at UPC?	Does the curriculum and UPC research respond to ensuring the human right to water?

3.1 Assessment of the course

In order to evaluate the course, two explicit reflexive questions are asked to the students: *What have I learned in this course?* And, *What do I think about the course* *(structure, organization, timing, projects, etc.)?* The results of the students' reflexions have been clustered in tables 2 and 3.

Table 2. Reflections of students about their learning

Topic	Relevant comments from students
Research methodologies	- *Qualitative and quantitative approaches are needed to see beyond the numbers.* - *I learned the relevance of qualitative aspects as we learned more from direct interaction with people than with quantitative data obtained by "R software".* - *The management of relations with qualitative research, which is not usually taught in tech universities, has been very stimulating* - *Qualitative data from interviews is a very inspiring process*
Transdisciplinarity	- *I have learned the relevance of stakeholders and the role they play.*
Real-life projects	- *To participate in a real project and to be in touch with real stakeholders has been very interesting* - *I liked to work in real projects*
Mutual learning	- *We learn to work with people from different disciplines and to improve our communication skills when working with professionals with different project management schemes* - *We learn to be more tolerant with our group mates that have different backgrounds and ways of working.* - *The most valuable point was the interaction with stakeholders from other disciplines, listening to their points of view and experiences in the topic.*
Robust knowledge	- *To realise that the different needs and concerns of stakeholders may shake the project process.*

Table 3. Reflections of students about the course

Topic	Relevant comments from students
Discussions in class	- *What I liked the most was the organization and group work in class, allowing us to listen and learn from each other*
Low directedness	- *There were many expectations at the beginning from all stakeholders and we felt a bit lost* - *The goal of the research should have been defined between the stakeholders which delayed the project, and was time consuming* - *The planning was confused and it took time to our self-organization with the stakeholders* - *I think that this course gives us too much freedom to make our choices, depending on which stakeholders we were discussing the topic with, the goal were changing…*

The main criticisms were related to the low degree of directedness at the beginning that for some was very frustrating, (the low directedness was deliberate in order to train students in dealing with stakeholders' different interests in real settings). In order to decrease the frustration among students, the course coordinators introduced an emotional intelligence workshop in the course

3.2 Emotional intelligence workshop

The module aims to allow students to obtain some experiential knowledge related to emotional intelligence and what the related competences are. These interpersonal competences, related to emotional intelligence are rarely included in curricula, although they have been widely studied and claimed [21] [22].

The workshop (2.5 hours) it starts with a framing theoretical introduction about emotional intelligence [23], multiple intelligences theory and related competences, always within the framework of sustainability [24] [25]. After that they participate in some exercises or dynamics proper to therapeutic theatre. The module follows the thread of the 5 domains of emotional competence: emotional awareness, emotional regulation, emotional autonomy, social competence, skills for life and well-being.

Participants recognize in an experiential way what the emotions involved in each of these domains of Emotional intelligence are, self-competence in all of them and how emotions can be perceived and expressed, understood, regulated and facilitated.

4 CONCLUSIONS

After the three years of the service learning programme, we have observed that students set out the importance of some topics and the difficulty they have to maintain them. Difficulties appeared at different points in the process, starting from the very beginning, when the problem formulation proved to be one of the most arduous task in the process. Another challenge arose with the accompaniment of stakeholders and the recognition of their role, during the whole process, because engineering students are not usually trained to work in wicked problems and moreover to work together with stakeholders. In this sense collaboration and communication with stakeholders was also challenging.

Finally, it is relevant to highlight that during the process students faced conflict and frustration within their team and with stakeholders. To face that, an Emotional Intelligence workshop was introduced which helped students to solve some paralyzing situations, which could have stopped the progress of the project. Therefore we suggest that engineering students need specific training in action research and conflict resolution. If not, they could collapse in frustration when dealing with real sustainability challenges.

5 ACKNOWLEDGMENTS

We would like to thank the students, faculty and stakeholders that has participated in our experience. We also thank the Municipality of Barcelona who this year is financing one of services in which students are participating under the framework of *Grants to institutions dedicated to the field of justice and the global international cooperation 2016*.

Opportunities To Share Ideas & Practice Among Engineering Education Initiatives

G A Thomson
Co-director Aston Stem Education Centre (ASEC)
Aston University
Birmingham UK
E-mail: g.a.thomson@aston.ac.uk

ABSTRACT

Globally there are a significant number of engineering and STEM related initiatives and organisations with each organisation having a particular emphasis, audience or approach regarding development of education in these fields.

All however aim to share ideas and best-practice among engineering educators so improving the overall learning experience of their students. By analysing the nature of the organisations it is hoped synergies can be found to more formally encourage organisations to share ideas while still retaining distinct identities and focuses.

At the SEFI 2016 conference in Tampere the issue of exploring and developing links between SEFI and CDIO (Conceive, Design, Implement and Operate) was raised.

This paper will share work being done towards a SEFI (European Engineering Education Society) position paper to improve the links between it and the CDIO initiative.

Conference Key Areas: Curriculum Development, Engineering Education Research, Attractiveness of Engineering Education

Keywords: SEFI, CDIO, Collaboration

INTRODUCTION

Around the globe there are a number of organisations and initiatives focussed around supporting and developing engineering education at which recognise the distinct demands, expectations and goals of the discipline.

Each organisation will have its own particular remit which may be focussed around specific branches of engineering, may be geographically focussed or may have particular emphasis such as engineering education research, practical implementation or focus on aspects such as technology to support education.

With pressures on academic staff to often focus their personal development around scientific and technical research, Engineering Education innovation is often characterised by small numbers of individuals working in the field in their own institution. The involvement of particular universities in these organisations is often dependent on key individual academic's personal contacts, capacity and aspirations.

While this is understandable, there could therefore be a tendency for parallel communities to develop which miss some potential synergies to support their members.

At the 2016 SEFI conference in Tampere there were a number of discussions regarding opportunities for closer collaboration between the European Society for Engineering Education (SEFI) and Conceive, Design, Implement and Operate (CDIO) with a view to developing a corresponding SEFI position paper.

This paper looks at these two organisations and draws together some thoughts on opportunities for collaboration.

1 ENGINEERING EDUCATION ORGANISATIONS

1.1 The global landscape

Globally there are a number of engineering education initiatives including the American Society for Engineering Education (ASEE), European Society for Engineering Education (SEFI), International Society for Engineering Pedagogy (IGIP) and Conceive, Design, Implement & Operate (CDIO).

For the purposes of this paper, the focus will be on the relationship and synergies between SEFI and CDIO.

The reason for focussing on these initiatives relates to overlapping but distinct educational and geographical focuses which offer potential synergies while still acknowledging the different strengths and objectives of each initiative.

2 SEFI AND CDIO

2.1 SEFI

SEFI (Société Européenne pour la Formation des Ingénieurs / European Society for Engineering Education) was established in 1973 in Belgium by a consortium of 21 European Universities from 6 countries with a mission *"To contribute to the development and improvement of engineering education in Europe and to the enhancement of the image of both engineering education and engineering professionals in Society"*. [1]

It lists a number of objectives including acting as a networking organisation among academics, industry and international bodies, serving as a forum to develop and influence policies related to engineering education and to contribute to the development and the improvement of higher engineering education.

SEFI offers membership as an individual, an institution, on a corporate basis or an associate basis – typically professional bodies, non-European organisations, student groups etc. At present SEFI has around 130 institutional members who pay an annual subscription to support the upkeep of the organisation.

SEFI runs an annual conference and is also responsible for the European Journal of Engineering Education. Organisationally SEFI is run by a council with responsibility for specific themes devolved to 11 working groups. These thematic groups have a range of responsibilities such as subject area (Mathematics, Physics, Sustainability, Ethics), operational aspects (Curriculum development, Quality, Online education) together with a range of other areas (Gender & Diversity, Education Research, Lifelong Learning).

These groups are then charged with developing their respective fields through projects, position papers and through the support and review of papers to the annual conference. Recent position papers emerging from SEFI include those on skills (2015/16) and those on the accreditation of engineering education (2012).

2.2 CDIO

CDIO emerged toward the end of the 1990s following thinking at the Massachusetts Institute of Technology's (MIT's) aerospace group which showed concerns among engineering employers that graduates emerging from Universities were often strong in engineering science but tended to lack many of the practical and personal qualities required by industry. While voiced at MIT, this was quickly seen as a global issue and a reflection of the culture of Universities moving toward a research driven agenda which in turn informed staff appointment and other strategic decisions.

By the turn of millennia a consortium involving MIT and a number of Scandinavian Universities began to develop the CDIO approach centred initially around a syllabus focussing on "what to teach" based on consulatation with stakeholders. Later 12 standards were created which tended to focus on "how to teach" with the focus being on active and project based approaches and continuous improvement of provision in an effort to draw out many of the perceived deficiencies in conventional graduates. The Conceive, Design, Implement and Operate (CDIO) was coined to reflect the sort of stages a student or graduate engineer might go through in the holistic solving of a typical engineering problem. [2]

At the time of writing, the initiative has grown to around 130 institutions globally, organised into 7 geographical regions. The initiative annually organises a main summer conference, a Fall (Autumn) meeting together with at least one meeting held by each region per annum.

Membership is at institutional level and carries no subscription cost. Potential new members are expected to benchmark themselves using a 0-5 rubric on each of the CDIO standards and present their plans at a regional or international meeting. There is no requirement to score any particular number of points against the standards however the CDIO organising council expect to see commitment to the CDIO approach, senior management support from their institution and a clear indication of how they would hope to participate in CDIO activities going forward.

For a typical CDIO member, initial involvement may often be triggered by a desire for their institution to make a step-change away from relatively traditional programmes to ones with a more holistic, active and project based approach. The CDIO standards and networks can then be used to help manage, measure and inform this change process.

For more established members, CDIO perhaps takes on a more conventional form, acting as a network for sharing best practice and innovation. In recent years a stronger focus has been made in regard to developing stronger engineering education research rigour and methodologies with the aim to provide continuing benefits to more long standing members.

Table 1 : A comparison between SEFI and CDIO

	CDIO	**SEFI**
Established	2001	1973
Institutional Members (Global/Europe)	~130/~75	~133/~133
Membership	• Institutional only (No fee, elected following successful presentation showing commitment to CDIO principles)	• Institutional • Individual • Industrial • Associate (eg. Professional Body, Industrial Organisation) • All by subscription
Organisation	• CDIO Council • 2 Co-chairs • 6 Members at Large • 7 Regional leadership teams	• SEFI Board of Directors • 21 members plus President & 2 Vice-Presidents

Events	• Main Summer Conference (June) • Fall Meeting (November) 1-2 Regional Meetings per region / per year • Regular TELECONS	• Main Summer Conference (September) • Working group events • Board meetings
Publications	• CDIO Conference Proceedings • Fall and Regional Meeting Documentation	• SEFI Conference Proceedings • Annual Report • EJEE (6 issues pa)

3 MEMBERSHIP AND FOCUS

3.1 Membership

SEFI has around 130 institutional members in Europe, while CDIO has around 80 members within its European and UK & Ireland regions, with a further 50 or so institutional members around the globe. The memberships of both of these organisations has grown organically over the years since their respective launches.

More detailed analysis of the breakdown of the memberships shows some interesting patterns and opportunities. [3], [4]

Fig. 1 shows the membership breakdown for some of the most heavily involved nations. It can be seen that there are a number of observations which can be made.

- Institutions typically belong to one or other but not necessarily both despite the possible overlapping and complementary opportunities afforded by this.
- There can be an apparent geographical bias toward SEFI (eg. France), or CDIO (Russia) which is likely due to history or local influences in each case.
- The membership levels of both institutions do not necessarily correlate to the number of engineering education providers in each country. Thus Finland and Sweden have a similar number of members of SEFI and/or CDIO as much larger countries such as France, Germany and the UK.

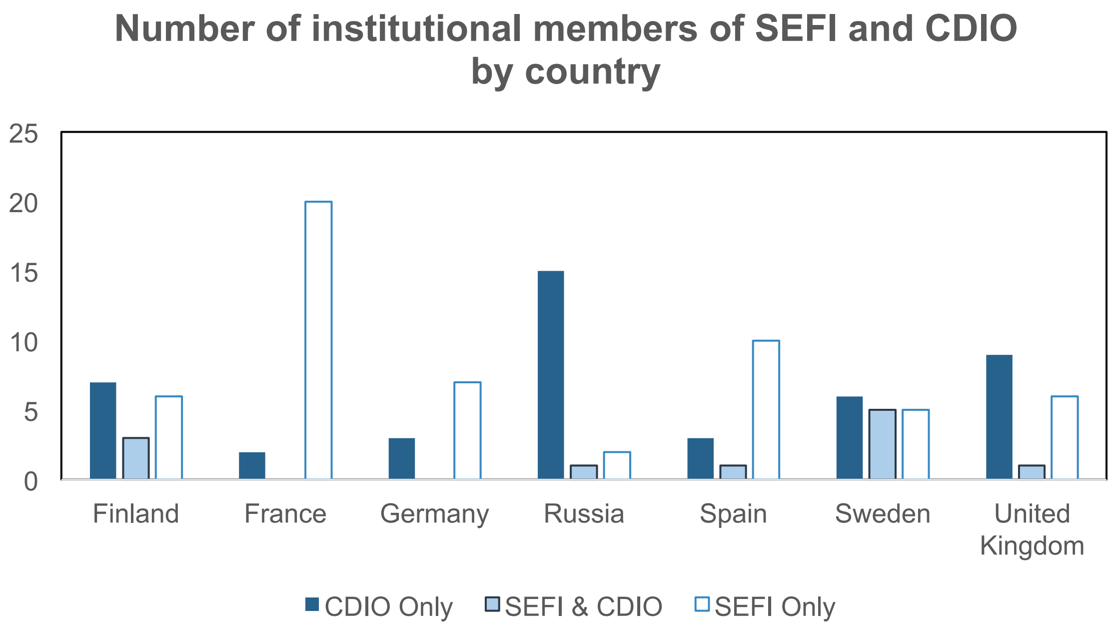

Fig. 1 . Number of institutional members of SEFI and CDIO by country

To reinforce the independence of the two organisations, *Fig. 2* shows the degree of overlap between the two organisations within Europe. It is notable that only around 10% or institutions holding membership of either organisation formally participate in both.

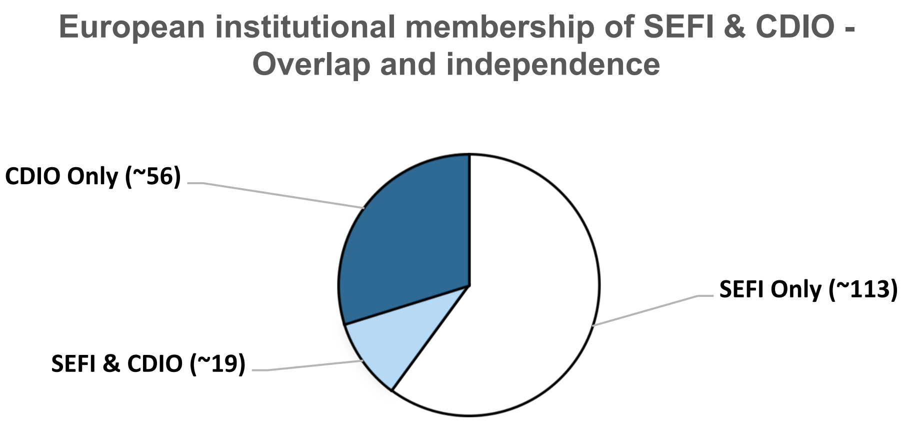

Fig. 2. European institutional membership of SEFI & CDIO - Overlap and independence.

It is also observable that both organisations have scope for growth in some of the larger markets should they choose to. As an example *Fig 3.* shows the extent of CDIO and SEFI membership within the UK market showing only around 10% of institutions awarding engineering degrees are members of either organisation. In the UK market, there may be particular appetite for growth with the introduction of the "Teaching Excellence Framework" (TEF) which has put some pressure on Higher Education providers to develop their approaches to learning and teaching. [5],[6]

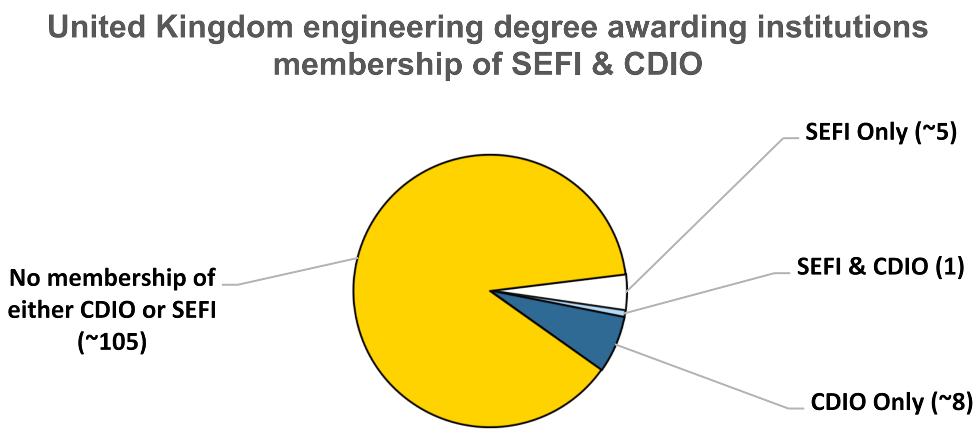

Fig. 3 . United Kingdom engineering degree awarding institutions by membership of SEFI & CDIO

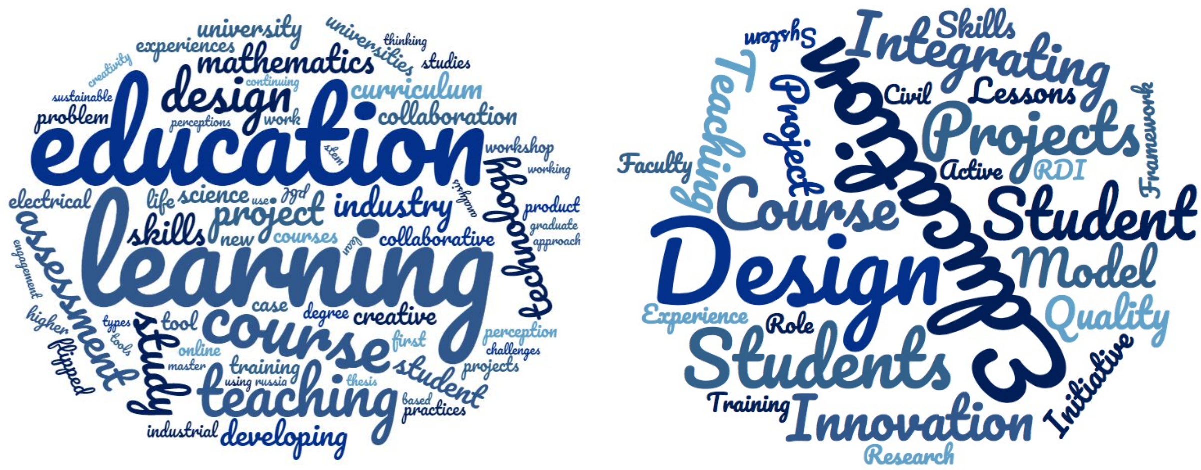
3.2 Focus

Both SEFI and CDIO have annual conferences where they invite members and any other interested partners to share their latest ideas, findings and research. In 2016 both conferences were held in Finland. In June the CDIO conference was held at Turku University of Applied Science where just under 100 papers were presented, while SEFI had their annual gathering at Tampere University of Applied Science in September with around 150 papers.

As a means of assessing the interests and directions of the participants of the two initiatives a survey of the titles of the papers and posters was carried out. [7], [8]. *Fig. 4* shows word clouds generated by the paper tiles from the two conferences. Words appearing only once or twice in the conference titles were omitted for clarity.



(a) : SEFI 2016 *(b) : CDIO 2016*

Fig. 4 . SEFI and CDIO 2016 conference paper title comparison

While CDIO was removed from its cloud it can be seen that the emphasis of the papers presented at both conferences were along similar lines and almost certainly would be of interest to each other's audiences.

4 POSSIBLE WORKING ARRANGEMENT & POSITION STATEMENT

Engineering education is a highly dynamic field and it is both challenging and rewarding to develop students who are not only encouraged and engaged in their studies of the discipline but once graduated, do so with not only the underpinning skills and knowledge required of a new engineer but do so with the ability to continue to evolve and develop through their career. Both SEFI and CDIO share these ambitions and so, while recognizing each as a distinct organisation, a greater awareness of what each has to offer, gives the chance to strengthen both. The following proposals are suggested as the basis of a SEFI working paper on their relationship with CDIO.

- SEFI recognises the approach of CDIO and that the framework of the CDIO standards and syllabus is a strong but flexible framework on which to transform programmes to ones which better meet the needs of industry.

- That both organisations have a strong history and ongoing innovation in engineering education research and that by sharing practice and developing initiatives in this area can only be positive. This is exemplified by a special edition of the SEFI run European Journal of Engineering Education focussed on "Scholarly Development of Engineering Education – the CDIO approach".

- That by sharing engineering education research proposals across the joint SEFI and CDIO networks, there is a much greater chance of finding like-minded partners, giving stronger overall partnerships, greater likelihood of securing funding and better overall project outcomes.

- That all engineering education specialists face a range of common practical pressures related to demands on staff time, expectations and budgetary and resource concerns. By working together SEFI and CDIO have greater critical mass to help influence the decision makers at institutional and governmental level to recognise the value and importance of engineering education.

- That both organisations have their own distinctive profiles and objectives and while sharing many core values, each offers the practising academic, support and tools to help them achieve their personal and institutional objectives.

- That, as exemplified by the 20 or so institutions holding memberships in both SEFI and CDIO, involvement in both institutions is a positive experience.

- That to make such interactions possible both CDIO and SEFI should be open to joint initiatives and offer platforms to raise awareness of each others activities both among existing members but also to the sizable engineering education

ABSTRACT

Energy consumption has been essential for Nations' development. Developing countries are highly populated and growing at a faster pace than already developed ones. Their willingness to reach a higher state of development is natural, which will inevitably mean the need for huge amounts of energy and resources. Moreover, they will generate huge amounts of gaseous and liquid effluents, and of wastes, triggering a need for much more efficient and cleaner technologies. Developed countries, however, face other problems, as they have established technologies, strategies and policies that are hard to change. Therefore, changing attitudes and strategic planning is vital to achieve a sustainable world. This change of attitudes is hard, and extremely dependent on the existence of a new kind of professionals who can, not only understand the diversity of problems and their implications, but also act as the link between the several *specialists* who can solve only particular problems. This calls for a multidisciplinary training at the higher education level, which has not been favoured. In this paper it will be discussed how to introduce in the engineering curricula the tools to educate such professionals, and how this strategy can be used to distinguish this

new generation of technicians.

Conference Key Areas: Sustainability and Engineering Education, Curriculum Development, Skills and Engineering Education

Keywords: Curriculum Development, Engineering Education, Environmental protection, Renewable Energy, Sustainable development, Sustainability

INTRODUCTION

The energy-based development has driven Nations to an exponential growth in energy consumption. The fossil derived energy is becoming scarce to fulfil all the energy needs. Besides, the associated emissions and environmental impacts are driving scientists and decision makers towards both a new model of development based on renewable energy systems, as well as on more efficient energy systems. However, both have brought new challenges: a significant part of renewable energies is intrinsically unpredictable and presently only can be used in a low percentage, as the electric paradigm is based in control. New appliances are now not only more efficient but also nonlinear loads, because of the introduction of electronic controllers, which brought negative impact on the electric energy quality.

These evidences show that not everything that is renewable will be sustainable. *The Beauty* of being apparently more environmentally friend also causes problems that need solution. On the other hand, the non-renewable energies cannot be considered as *The Beast*, as their total elimination from the actual energy system cannot be achieved without a deep change of both human behaviour and of the energy system. The whole system has to be analysed in a life cycle thinking perspective, where non-renewable energy sources must be considered as one essential piece to supply the failures of the renewable sources, and all the appliances that are developed to reduce the energy consumption are submitted to deep analysis of their impacts.

To analyse such problems, two different approaches can be used, though, any of them is based on the existence of professionals who are multidisciplinar in nature. The first approach is to build teams that are leaded by senior experienced engineers (SEE), used to work in large teams of specialists; the second approach is to form teams that are leaded by junior multidisciplinary engineers (JME), used to analyse and discuss problems in multidisciplinary teams, including in their analysis not only the direct impacts but also the impacts that occur in different dimensions, and to anticipate potential problems. SEE have high associated costs and may have tendency to overestimate or underestimate potential problems. JME have lower associated costs and a natural willingness to let specialists present the advantages, whereas they can themselves anticipate the drawbacks.

Thus, multidisciplinarity is now an advantage to solve problems such as the storage of surplus renewable energy produced for later use, or its immediate distribution to where it is needed by using smart grids, the mobility and transportation in modern mega cities, the integrated waste and effluents treatment with energy and/or biofuel production, or even the construction of Zero net Energy Buildings (ZEB), among others.

Therefore, this new model of development relies on a new class of environment and energy professionals, who are able to relate their particular expertise with all the other areas involved, and to understand the impacts of such systems. The time to explore concepts and emerging technologies in a collaborative way has just started, bringing together engineers, researchers, decision makers and professionals from different areas. In fact, we can perceive that new and tighter targets towards sustainable development have been set by several countries, as from the Paris Agreement in December 2015. However, the path to reach them is a sensitive matter concerning to each country and no rules were set. Thus, more than ever, in this very moment it is critical to educate professionals who are able to plan truly sustainable systems.

We will discuss how to introduce in the engineering curricula the tools to educate such professionals, and how this strategy can be used to distinguish this new generation of technicians.

1 DEVELOPING AN ENGINEERING CURRICULUM

According to Feisel and Rosa [1] "*Engineering is a practicing profession, a profession devoted to harnessing and modifying the three fundamental resources that humankind has available for the creation of all technology: energy, materials, and information*".

The Bologna Declaration on Higher Education (HE) [2] was the turning point when all the Portuguese HE Universities and Polytechnics had to change the model of their engineering curricula to a 3+2 years plan of studies. Up to then, different models co-existed, with 3+2 years in the Polytechnic and 5 years in the Universities. Nowadays, the 3 years graduation as a Bachelor in Engineering (*Licenciado em Engenharia*) allows one to develop a professional activity as an engineer with limited intervention, if the graduate comes from a Polytechnic. However, Universities that essentially have adopted and integrated model offering a 5 years course with an intermediate graduation as Bachelor in Sciences of Engineering (*Licenciado em Ciências de Engenharia*) in the 3rd year, do not recognize that these graduates have any engineering skills. The last 2 years are part of the graduation as MSc in Engineering, including a Master Thesis corresponding to at least 30 ECTS.

1.1 Graduation in Engineering

It has been a matter of discussion, if engineering curricula should start with a focused or with a comprehensive plan. The main advantage of the comprehensive plan, where students must contact with several matters, is that graduates learn, from a very early stage of their lives, how to interact and consider the different problems. However, they do not have enough time to deepen the knowledge, and therefore they may not really have the tools to understand the impacts of their decisions. This partially explains the relatively high rate of Dropouts in such courses.

On the other hand, the focused plan has the advantage of providing the students with enough tools to start a professional activity in a particular field of engineering, such as mechanical engineering, electrical engineering, civil engineering, geotechnical engineering, chemical engineering, etc. Being focused, students may not be aware of the need for interaction with other specialities, and therefore they may not develop the necessary skills for teamwork (not group work).

However, in our experience, we believe that younger students have generally much lower degree of autonomy and maturity that is needed for succeeding in graduation under the comprehensive plan.

1.2 Post-graduation: the MSc in Engineering

Depending on the HE system, the number of students who already are developing (or have developed) professional activity when they are studying in the MSc program can be substantially different, whereas in the Polytechnic system this number can reach up to 90% [3], in the University system it is usually much below 25%.

This not only affects the *style of learning*, but also the motivation, the time available to attend classes and to study, and specially, the matters of interest. In fact, professionally active students often pose questions intrinsically linked with *problems* from real cases in their own jobs. This is not only important because the school acts as a trigger for the *solution* but also because the remaining students in class recognise the global *importance* of a given subject and increase their *trust* on the educator.

Additionally, having developed professional activity can be used as case study, or as a source of interaction between Academy and Industry, helping the creation of strong and long lasting ties between them.

The higher degree of maturity of the students in this 2nd cycle of studies allows one to address bigger challenges, as those that are derived from multidisciplinary problems. This is the reason why it should be preferred to organize the HE courses in engineering in such a way that the 1st cycle is focused in a particular field of engineering and the 2nd cycle can be more comprehensive.

2 EDUCATING ENGINEERS FOR SUSTAINABLE ENERGY SYSTEMS

Having decided that it is preferred to use the focused+generic plan in the 1st+2nd cycle, it was thus decided to plan a MSc in Sustainable Energies. This MSc program [4] receives graduates from any 1st cycle in Engineering, as well as graduates from other fields of sciences. However, the later may have to acquire skills in particular areas, such as Thermodynamics, Physics, etc.

2.1 Designing the course plan

The course plan was built upon multidepartamental teamwork. Representatives from all engineering departments at ISEP were involved in the design of this course, bringing their expertise in the particular scientific area of engineering as well as their knowledge on the scientific problems under study in the energy field. Already at this time, it was privileged the participation of those who were able (or who were willing to make an effort) to address and discuss mustidisciplinary problems.

The result was a set of 8 mandatory plus a set of 5 out of 19 elective disciplines, each accounting for 6 ECTS, followed by a final Master Thesis (42 ECTS) [4].

2.2 Mandatory courses

The objectives of the mandatory courses is to provide all the students with the basic knowledge and skills in the energy sector, with a particular focus in the Environment and Natural Resources; Renewable Energy sources; Transfer Phenomena; Dynamic Control Systems; Management and Evaluation of Environmental Impacts; Energy Conversion Systems, and finally, Economical Analysis of Environment and Energy Projects. As the MSc receives students from different backgrounds, sometimes this means that the mandatory courses start with a kind of brief revision of basic concepts, and then they deepen the necessary disciplines.

2.3 Elective courses

These are the courses that allow each student to build his own professional profile, according to his preferences and style. Therefore, it is possible that a student chooses courses more oriented to higher energy efficiency, to sustainable buildings, to combustion systems, to biofuels production and characterization, to emissions treatment and minimization, air conditioning, distributed energy systems, energy markets, or even entrepreneurship, among others. The electives are focused courses, usually appealing to previously acquired base knowledge.

3 DISCUSSION

It should be emphasized the high acceptance of this course and the enthusiasm of the students who attend it. Partly this is due to the fact that energy and sustainability are current and modern themes, for some, they are really a hot topic. However, students realize that there is still much to be developed in several areas of work and they genuinely intend to contribute with their attitude, efforts and skills.

In fact, it is motivating to develop solutions that contribute to a more sustainable world (The Beauty) but an intervention in an area has a chain effect in the system (The Beast), being only possible to solve the problems stepwiselly.

When we take the example of public lighting using LED-based lamps, we know that the replacement of conventional lamps with LEDs resulted in a lower energy consumption. However, LED lamp power supply has a highly non-linear behaviour, causing harmonic distortion and greatly increasing electric power distribution losses [5]. Public lighting is an Electric Energy System area, whereas the lighting power supply belongs to the Electronics Engineering area. Furthermore, other problems arise from the extensive use of LED lamps, as is the case of the quality of light and the effects of single wavelength on human visual comfort (Electric Energy Systems), the problem of natural resources needed to supply the required amount of lamps (Mining, Geotechnical and Environmental Engineering), or last but not least important, the problem of the disposal and elimination of the spent LEDs when their end-of-life is reached (Environmental planning and management).

When we take such a kind of approach to the Electronical appliances, we notice that it is mandatory to apply a Life Cycle Analysis (LCA) methodology to the production of any new equipment in a large scale. The solution to this problem can only be designed through the collaborative work of professionals of all involved areas.

As referred in section 2 of this paper, the Master in Sustainable Energies was carefully designed in order to develop the technical and interpersonal skills, with a broad scope of disciplines taught by professors from six engineering departments of ISEP, who have succeeded in working together in the same collaborative path.

As an example of the success of this MSc, we can point out a geotechnical engineer who is working today with Bosch, a mechanical engineer who is working in a biofuels plant supplier or a civil engineer who is working in the wind energy sector, all of them as Master graduates.

4 CONCLUSION

The Master in Sustainable Energies has graduated professionals in the Energy sector with a focus in the engineering aspects, from 2011. The course has a comprehensive structure, and has received growing interest, not only at a National but also at an International level – Brazilian, Indian, Polish, German, Latvian, French, Spanish, Italian, Syrian, Nigerian, etc., students. Its graduates are all developing professional activity, regardless of their primary 1st cycle graduation program, in the energy sector.

What is a Sustainable Curriculum?

Re-thinking the Modes of Curricular Existence

B. Tabas
Associate Professor
ENSTA Bretagne
Brest, France
Brad.tabas@ensta-bretagne.fr

ABSTRACT

The following intervention proposes an alternative way of thinking about curricula. It argues that current theorizing about curricula tends to confuse sustainable course contents with a sustainable curriculum. Drawing on object-oriented ontology and actor network theory it offers a way of rethinking curricula to better attend to the real challenge of sustainability.

Conference Key Areas: Curriculum Development, Sustainability and Engineering Education, Ethics and Engineering Education

Keywords: Sustainability, Curriculum Theory, Object Oriented Ontology

INTRODUCTION

Rethinking curricula from an ecological point of view demands much more than merely adding courses on sustainability-related themes. It requires a revision of the way that we think about the nature of curricula, an open reconceptualization of what a curriculum might be.

Almost all thinking on curricula, like so much else that is inherited from the western tradition, is rooted in an idealized conception of the human being which sees minds as separate from the world that surrounds them. Humans are not entangled in things, they are not part of the world or an ecosystem. They are radically separated into mind and body, or, at another level, into society and nature, or the study of discourse and the study of things. This mode of thinking supports what might be called superficially sustainable curricular reform. The superficially sustainable engineering school has modules on sustainable manufacturing, it has researchers working on producing green energy, classes on sustainable cities, and so forth. In accordance with broadly accepted ideas about how to form a sustainable curriculum, the teachers at this school work across disciplines, making a consistent effort to make students aware of environmental problems. [1] In addition to course work, students at this school find themselves immersed in a culture which reinforces and generates sustainable values. The school conforms to the definition of a sustainable curriculum offered by the UK Engineering Council and other such organizations. In other words, it fosters an “understanding of the requirement for engineering activities to promote sustainable development”. [2] We should be happy such schools exist. However, if this is our paradigm for a sustainable curriculum, then we have a major sustainability problem. Why?

One can intend to teach about sustainability, without that curriculum being sustainable. Between the intention to teach something and its enactment, **there are always material conditions that intervene to make that happening of the curriculum possible. These conditions, despite the strain that it may place on our traditional ways of thinking, need to be seen as part of the curriculum.** *Rather than asking whether the courses are about sustainability, we need to explore whether the entire network of material parts and multi-agent interactions making those courses possible is consistent with sustaining life on earth.* Every sustainable development curriculum implies classrooms, books, computers, and other supports proximate and distant, including connections to various infrastructures and networks—including intercontinental fiber optic cables, highway systems, global markets, and power grids. This is true for brick and mortar institutions and for digital classrooms. These supports form part of the indispensable conditions of existence for any curriculum; these material networks *are also the curriculum*.

Reflecting on curricular sustainability in this broader sense is challenging, because it undercuts the legitimacy of the model of sustainability thinking presented above. Our superficially sustainable curriculum involved lessons transmitted by textbooks. Books are made of paper, and that paper comes from trees, which in turn come from forests. These forests might be managed sustainably… or they might not be. In most cases, neither of these things will be transparently evident to students reading about the benefits of reducing, reusing, and recycling. Say we replace books with computers or digitized documents of some kind. We often think that digital documents are more sustainable than paper ones, we feel like we are doing something environmentally virtuous when we do not print out a document but rather consult it electronically. But also means that we overlook the material reality of computing. What is a computer? It is rare that we think deeply about this question, because most of the time we do not look at or into our computers, but rather through them, considering only the information that they contain. [3] Yet as anyone who has ever seen Edward Burtynsky's photos of e-waste recycling sites in China would know, computers are much more than streams of information. They are generally made of plastic (a petroleum by-product) filled with various pieces of silicon and rare metals, some of which are non-toxic and recyclable, others of which are toxic, non-recyclable, and frankly dangerous for human health. [4] Many of these materials are sourced or disposed of in ways that are neither sustainable nor humane (consider the case of coltan, one of the key materials employed in the making of smartphones, and the cause of a great deal of violence against both human beings and the environment). [5] A computer is always either immediately or via radio waves attached to two cable systems, one of which brings it power (the source of which may well be combusting coal), another one distant information. This latter implies links to fiber optic systems and server farms world-wide, all of which once again consume potentially non-sustainable energy sources, while potentially (in the case of undersea cables) interfering in marine ecosystems. [6] To these considerations we can also include reflections on the sources of heat and light in the classroom, or the means of transportation by which students come to and from their homes or dorms to the classrooms.

Wholly other sets of connections also inflect the real sustainability of a classroom and ought to be taken into account. These connections are not primarily material like the ones mentioned about, but include socio-material networks like the economy.

Everyone knows that schooling is expensive. Top schools need to have significant funds to enact their curricula (and to compete for places on the Shanghai ranking). But where does this money come from? We can safely assume that the sustainability of the tuition money in elite schools will roughly mirror the sustainability of the sources of high-income employment within society. It is mostly the parents' jobs or the student's downstream employments which will generate the revenues that cover tuition fees. Given that so many of the world's largest and richest corporations are unsustainable (four out of the top five grossing corporations worldwide are petroleum or energy companies) we can conclude that at least part of the money paying for the happening of any curriculum is unsustainable (the case is only slightly altered in the case of public school systems, since the wealthiest corporations pay the most taxes.) Aside from student tuitions, most major universities derive their funds from endowments and research contracts with corporations and governments. Are these funds sustainable? The recent student movements protesting the high percentage of fossil fuel stocks in the portfolios of many top American universities show that this not yet the case. [7] What about the research contracts? It is more than likely that any top engineering school with some courses on sustainable development will also have researchers working on projects funded by the fossil fuel industry, with it being no stretch of the imagination that these are *the same researchers* teaching courses on sustainability. As Naomi Klein and others have shown, highly visible investing in sustainability research has been one of the most frequently used greenwashing strategies deployed by major companies in the petroleum and transport industries. [8] Of course, one can reply to this analysis that the material contribution of unsustainable industry to increasing sustainability actually amounts to a net demonstration that the curriculum is sustainable, since investments are flowing from the unsustainable to the sustainable. But what one cannot do is disregard this level of complexity when considering curricula.

The economic does note exhaust the complexity of curricula, however, particularly if we are thinking about engineering schools. Unlike liberal arts institutions, engineering students spend a great deal of time interacting with technological devices. Whether these be robots, computers, or nanoscale microscopes, engineering schools would not exist without technologies. Based on the above we might be tempted to analyze the sustainability of these technologies via purely material considerations. But if we did so, we would miss out on what might be called their architectural telos. This is a twofold category, one with respect to how technologies condition us, and one with respect to how the current design of a technology conditions future redesigns of the same. Both aspects come into play when we consider the direction in which any curriculum is likely to evolve, and both aspects can to be considered part of the sustainability of an engineering curriculum. *The design of current technologies impacts the design of future technologies and so plays a role in the sustainability of a curriculum.*

It turns out that assessing or even describing sustainable curriculum is harder than making up a curriculum about sustainability. The examples that I have given are not exhaustive but rather suggestive of the real complexity of curricula. Serious attempts to think about the sustainability of engineering curricula must not flee from this complexity but rather embrace it. Doing so poses conceptual and methodological challenges, may leave us feeling lost or confused, may seem to alienate us from what we thought was reasonable and certain. But failing to even attempt to rise to the challenge or brushing aside the concerns raised by deeper questions are sure recipes for failure.

1 RETHINKING CURRICULA

1.1 A Curriculum as an Enacted Ecosystem

A sustainable curriculum possesses the long-term means for its perpetuation. A curriculum that is sustainable is sustainable on all levels, not just sufficiently sustainable to reassure us that we are trying to do something at the level of ideas. Thinking about curriculum that overlooks the question of long-term means by focusing only on ideas and pedagogical intentions is endemic, and this is precisely what we have criticized in the standard model conception of ecological curricula. In order to avoid shallow thinking, we must *view curricula from the point of view of their enactment as opposed to their content*. By enactment we intent the broader coming into being of a curriculum. This means that we abandon the subject-centered intentional understanding of curriculum that is and has been the norm. We must now consider the interactions between all of the things involved in making happen a curriculum as we normally intend the word. Material things, and not just human intenders are now actors. A curriculum is a particular kind of complex ecosystem, and it can be studied as one studies other ecosystems, albeit with an addition of the additional complexity introduced by the importance of intention and discourse in human interactions.

This is obviously a heterodox interpretation of the meaning of curriculum, though it is not an abusive one, even from the viewpoint of etymology. According to the *Oxford Latin Dictionary*, the word *curriculum* (a 2nd declension neuter noun) has the following definitions: the “act of running,” the “chariot,” the “course of action/heavenly bodies”, “lap, track,” and “race.” [9] Roughly half of these meanings refer to the aspect of the curriculum that interests us, namely the material conditions or the ecosystem in which the race occurs—the chariot and the track—and their influence on the happening of the race.

1.2 Anti-Anthropocentrism

Recent work philosophy in the philosophy of the social sciences, has suggested that we must move away from understanding society anthropocentrically. [10,11] Anti-anthropocentrism in this sense implies that we must not overly privilege what social actors think that they are doing when we analyze what happens in social groups. Our ideas and intentions are merely one level in the complex tangle of interactions that make up any kind of social happening. A computer, a test bench, or the geographic location of a school, can thus be thought of as equally important to the happening of a curriculum as the ideas of a pedagogical visionary like MIT’s William Barton Rogers. A curriculum is thus not just the sequence in which ideas and values are impressed upon human minds, nor any accounting that might be made of those ideas and values, but something much more complex and indeed ambiguous. Our example above illustrates this perfectly: is our curriculum sustainable or not? Yes and no, depending upon which perspective we privilege. One is tempted to eliminate one or the other aspects just to get a clear response. Yet a better reaction is to think about a way to create a meaningful discourse about this complexity, to find out a way of making sense of and attending to the complex and conflicting aspects and actors at work within the unfolding of curricula.

1.3 Theory versus Topography

We tend not to appreciate the complexity of things in part because so much of human practice is aimed at reducing complexity. Theories attempt to reduce complex happenings to simpler structures or essences that are taken to be the real of what initially appeared complex. They are intrinsically reductive. But what we need is not reduction but orientation. We need tools that encourage us to look a bit farther, to find out what is around the next bend, to prompt us to fill in details and aspects of curricula that we might otherwise miss. One method of preserving complexity while orienting ourselves within this complexity is cartographical or topographical. Topographies do

simplify to provide orientation, but they in no way suggest that the map is more real than the territory. The rewards for employing this kind of topographical approach
45th SEFI Conference, 18-21 September 2017, Azores, Portugal
involve greater sensitivity to difference and complexity, as well as a heightened understanding of the mereological relations between the curriculum and its constituent elements.

Because a curriculum is highly complex, involving mind-mind interactions, mind-object interactions, and object-object interactions, as well as variable dimensions of expression and latency, multiple degrees of conscious and unconscious awareness, fairly complicated metaphysical notions are necessary for its description. I therefore introduce the notion of the mode of existence. A mode of existence is a way of being that is complete but not total or exclusive. By this I mean that that mind-object interactions exist on a different plane than mind-mind interactions, that these interactions have play out along what seem to be independent lines of temporality, spatiality, and causality, and that both interactional nexuses are to be treated as equally real, precisely because the interactions between these two modes must both exist, and exist ambiguously. Understanding a curriculum involves elaborating its topography across multiple modes of existence.

In order to illustrate my point, we can consider abstractly the idea of the sustainable curriculum and its material reality. In terms of mind-mind interactions, all of the teachers and students might well believe that a curriculum is sustainable, without that curriculum being as sustainable as they think in object-object terms. As Etienne Souriau has pointed out, a typical theoretical gesture is to attempt to assign degrees of reality to the varying existential modes, essentially claiming that some are less real than others. [12] Yet just as it would be violent and even absurd to say to a depressed person that their perceived causes of their sadness were unreal, and that the real source of their depression is their serotonin levels, it is violent and absurd to claim any aspect of the curriculum as the real. Every mode of existence is characterized by a specific articulation of how actants can relate meaningfully with one another. It would be wholly possible (if contrafactual) to imagine that a curriculum was materially sustainable without anyone having ever intended this to be the case, just as it was the case that the curriculum that we initially imagined sustainable turned out not to be so, though the long-term evolution of both curricula would be different (but that would depend upon more factors than just the intention to make a sustainable curriculum).

2 FOUR MODES OF EXISTENCE

Contemporary philosopher Graham Harman has introduced a fourfold existential topography that can help us to direct our attention to the broad modal outlines of curricular existence. [13] I say broad outlines, because as we will see, every fundamental mereological framework (and that is to say every science, be it chemistry, physics, or curriculum studies) establishes a novel mode of existence as it codes meaningful elements within its discursive system. Nevertheless, Harman's work is interesting because of its relatively high level of ontological abstraction allows us to rediscover its broad outlines in other, more local, existential ontologies.

Harman calls the four primary modes of existence the "fourfold." According to Harman the fourfold is made up of two pairs, each of which is in tension with its other. [14] The first pair of modes he calls real objects and their qualities, and the second pair are sensual objects and their qualities. Rather than adumbrating the sense that he attributes to these terms, it seems more useful to introduce and explain the versions of these notions adapted to the study of curriculum. In what follows, I equate the

Harman's distinction between the real object and its qualities with the metaphysical and the material curriculum, while the distinction between the sensual object and its qualities are equated with the social and the subjective curriculum.

2.1 Metaphysical Curriculum

The **metaphysical curriculum** exists in a state that Harman describes as "withdrawn." It is primarily to be understood as a group of objects subtracted from their relations. These objects include both human beings and material things like buildings or books. No subject experiences or perceives this curriculum directly, no two objects interact with one another. No science or discourse about this curriculum is possible. The metaphysical curriculum in this sense is latent and remains latent, but it is the site from which all radical curricular becomings originate. It is at once a pure idea and the bedrock of material reality.

If we thus have nothing to say about the metaphysical curriculum, why then should we even mention it here? Most importantly, claiming that there is such a metaphysical curriculum affirms that there is a reality out there, a reality wholly independent from the human mind and the constructions of discourse, and that beings have a reality apart from those expressed in their relations. Stipulating an outside allows also for us to theoretically leave space for becoming, and to recognize non-human material agency. It can also, and likewise, be thought provide a metaphysical justification for the exercise of the principle of precaution as it is elaborated in the philosophy of Hans Jonas. [15]

2.2 The Material Curriculum

The material curriculum corresponds, in Harman's thought, to what he calls the real qualities of an object, and we can understand this to be the curriculum insofar as it is expressed in object/object interactions. Contrary to the metaphysical curriculum, the material curriculum is expressed (if it is not necessarily expressed to human observers). We might thus speak of it as available to science, but not necessarily present to science, and of course never present to science in precisely the same form that any discourse about this science might take. In fact, any account of the material mode will only be partial, only offered to knowing subjects through the mediation of a system of discourse and practices. Actor Network Theory-influenced science studies scholars have often—and with good reason—discussed material modes of existence as multiple. As Anne Marie Mol has illustrated, after having carefully studied production of knowledge and discourse around the material aspects of the patient's bodies within a hospital, via the study of blood chemistry, or cell cultures, or radiographic images, we end up having multiple bodies, since each technically assisted process offers insight into an aspect of the material that can only with difficulty be translated into terms equivalent with another. [16] This is because each mode of making discourse implies different material connections relative to the coming to discourse among objects. Let us note also that human bodies are also deeply entangled in the material curriculum. This is true in the sense that human bodies are involved in making sense of matter, but also in the sense that human bodies are affected by matter in ways that oftentimes elude or challenge sense making. It has been shown, for example, that chemicals emitted into the air by automobiles affect the development of children's cognitive functioning, leading to higher incidences of learning disorders and including ADHD. [17] As is evident, having affected children in the classroom, or, considering a larger time frame—affected teachers behind the lecterns—will affect the contents and the rhythm of the courses taught within an institution. But making sense of these changes, at least from a first-person point of view, must remain obscure. None of the people that are affected know what life would be like outside of their being affected. All would be affected differently by this differently were they aware of these material interactions. How they understand their being affected happens through a process of translation, via a making sense of one regime of signs (reflective personal experience) in terms of another regime of signs (scientific knowledge about brain chemistry). In a practical sense, describing a curriculum in terms of the material curriculum involves looking for spaces that can be measured, but which stands outside any accounting of human social actors regarding either their individual or collective intentions and understandings.

2.3 The Social Curriculum

The social curriculum is the curriculum as it exists in mental, social, or inter-subjective space. It is not necessarily the curriculum as it is consciously articulated by actors, but rather the unconscious within the discourses produced by conscious actors, or at least between actors interacting via sign systems. Within the social curriculum we can situate what some have called the “invisible” or “hidden” curriculum, we can also situate many of the dimensions of the curriculum brought out by Structuralist curriculum scholars such as Bernstein. [18] The social curriculum does not exclude the material, but includes the socio-material tangle that is the economy, as well as what Bruno Latour has called the Parliament of Things, namely the articulate results of human-non-human interactions such as scientific disciplines, as well as various phenomena associated with material signification. [19, 20] It can also include the symbolic, but unintentional meaning of various object dispositions, such as the meaning of chairs in a room or departments within campus buildings. The key feature of this curricular mode from the point of view of scholars striving to establish curricular topographies is its distance from the intentions of the actors involved in articulating it, it is thus available to what systems theorist and sociologist Niklas Luhmann calls second order observers. [21] For many, this is the most interesting dimension in curricular studies. Within this framework can discuss elements such as the effects of an environmental studies professor’s gas guzzling car on the lessons that he or she teaches, or study the ways in which Judeo-Christian ideas about the natural world structure the environmental values conveyed by an institution. It should be noted that just as in the case of the modes of material existence, each of these networks of connections within the social curricular mode of existence appears ontologically discrete, since they can only come to subjectivity through a specific process of enactment and translation. This means that we can look at the same social curriculum from the point of view of economic relations or gender relations, and both will yield insights into the sustainability of a curriculum, but neither will articulate in the same way the elements within the social curriculum. A topographic approach allows these various perspectives to co-exist and to co-inform our understanding of curricular sustainability.

2.4 The Subjective Curriculum

It may seem almost unnecessary to discuss the subjective curriculum, because it is this curriculum that has historically almost always been the subject of discussions on curriculum. The subjective curriculum is the *content* of a curriculum as it is articulated by a conscious subject aiming to construct a plan for teaching students. The subjective curriculum includes the visions of curriculum articulated by educators and administrators, not in their textuality or material reality, but as they themselves believe that they understand them. It also includes the signification of all the curricular supports and events—books, exams, even the symbolic importance of campus monuments—but seen only from the viewpoint of the educator’s intentions. More broadly speaking, and this is crucial for understanding the interest of the multi-modal model presented here, the subjective curriculum is any version of the curriculum that any subject—a teacher, a student, or a curriculum scholar—articulates. In the final instance, this therefore also includes any account of an institution's curriculum articulated by a scholar, including one using the methods here. That said, there is obviously a radical practical difference between considering the subjective curriculum as the total extent of the curriculum—i.e. speaking of a curricular vision or an intent to articulate a specific curricular vision—and recognizing that it is just the tip of the curricular iceberg.

3 Towards a Conclusion

The elements presented here prompt us to more fully describe the elements in existing curricula, but they do not explain how to form a sustainable curriculum. What then is the point of this exercise?

3.1 Studying Curricula

The general topographical oriented presented is really aimed at those seeking to carefully and scientifically describe curricula. This is important, since to a certain degree we cannot understand what our curricula are without carefully applying ourselves to this task. Considering each mode of existence in turn it forces us to explore the potential importance of that which may not appear to have meaning to the traditional curriculum theorist. This brings about a second benefit, namely the fact that a multimodal approach offers a richer sense of the meaning and lessons enacted by a particular curriculum. The key here is to note that unlike traditional thinking on curriculum, where one supposes that each institution has a single curriculum, this approach allows us to envision multiple and sometimes apparently contradictory curricula existing within the same institution. While paying attention to these additional levels of complexity may seem frustrating, it is crucial to note that it is only by acknowledging complexity can we hope to improve curricular sustainability.

3.2 Pedagogy for Sustainable Innovations

Assuming that we have taken the time to appreciate curriculum in all of its complexity, what do we do next? The first thing to do is recognize that we have already undergone an essential re-orientation—we are now operating not from ideas down, but from material signs on up. Deeply engaging with the material curriculum in all of its levels will yield ecological awareness, but it may also yield innovations. Solutions to environmental problems do not come out of thin air, but rather out of an everyday entanglement with environmental problems. The more profoundly our curricula set in motion processes of co-creation in which actors human and non-human engage with one another, the greater the likelihood that our curriculum actually tends towards being sustainable and producing sustainability innovators.

Sustainable design of products and services course: designing through materials' sustainability lenses

E-mail: Jordi.segalas@upc.edu

ABSTRACT

"Sustainability" in design is not a simple constrain that can be quantified and optimized in an engineering design. Issues of sustainability are inherently complex and wicked; their assessment requires acceptance of this complexity and working with it. Each aspect (e.g. environment, society, regulations, design, materials…) can be explored in a systematic way but the integration of the aspects to give a final assessment needs judgment and reflection, as there is no one single sustainable solution to a problem. Integrating the different articulations of Sustainable Development needs a holistic approach and stakeholder participation. How can we teach this to engineering design students in an efficient and effective way?

This paper presents the scheme of the Sustainable design of products and services master course and the ideas behind new teaching resources for Sustainable Development, designed for engineering design and materials science courses. These resources identify the complexity and transdisciplinary issues of sustainability and new methodologies and tools to help student understand and analyse them. This paper describes the course and the reasoning behind the resources, which include a method and a database of background information. The outcome is, inevitably, subjective, influenced by social, cultural and political background and therefore one requiring debate, but the method creates a common background of accepted facts on which an informed debate can be based. Since 2013, the course has been run at the Master in Sustainability Science and Technology at the Universitat Politècnica de Catalunya, providing experiences in a real educational setting. This paper summarises some of their outcomes in terms of learning, course design and participatory approaches in education.

INTRODUCTION

Since 1991, the Universitat Politecnica de Catalunya (UPC) has focused on introducing Sustainability education in all its engineering and architectural programs through two environmental plans and currently through the UPC Sustainable 2015 [1] plan.

Since 2013 the course Sustainable design of products and services has been run in the Master in Sustainability Science and Technology at the Universitat Politècnica de

Catalunya. Next sections will present the experience which may help when introducing new teaching for Sustainable Development, designed for engineering design and materials science courses.

1 SUSTAINABLE DESIGN OF PRODUCTS AND SERVICES COURSE

The Sustainable Design of Products and services (SDPS) is a 5 ECTS course offered at the third semester (out of four) of the master degree in Sustainability Science and Technology at UPC.

2 COURSE STRUCTURE

The course uses constructive and community oriented learning for sustainable design. It is organized around three axes (Figure 1): Strategies, Tools and Projects. First, students are introduced to sustainable design strategies principles (Eco-design, Cradle 2 Cradle, Biomimicry, Product Service Systems, Design for Sustainable Behavior, Human Centered Design, Social design, etc.). Second, students use CES-Edupack software using the Advanced SUSTAINABILITY database tool and finally, students apply the tool to a contextualized project taking into consideration the sustainable strategies available. Students spent approx. 50-60% of the course time on the group project. They presented the progress after each project phase. Next paragraph focus in this methodological approach.

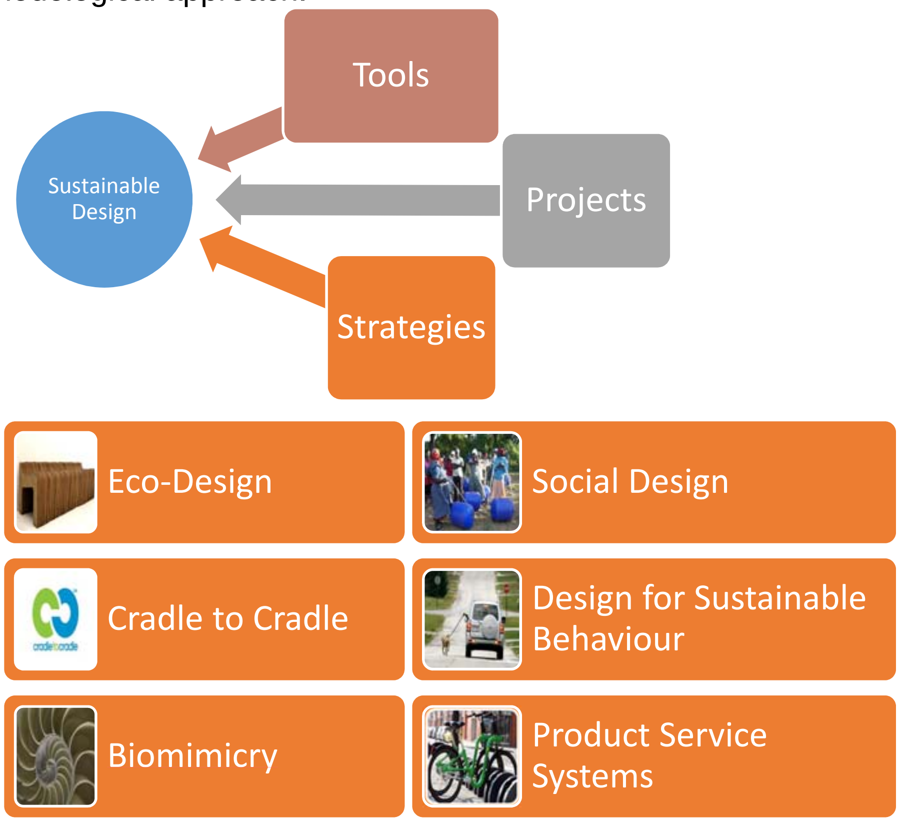

Figure 1. Main features of the course with sustainability design strategies.

3 METHODOLOGY

A “Sustainable Development” is one that contributes in an equitable way to human welfare and does so in a way that minimizes the drain on natural resources. Many academic, civil, commercial and legislative projects claim to do this – promoting biopolymers, carbon taxes, design for recycling are examples. Following Mulder et al.

[2] we shall refer to them as “articulations” of sustainable development. But how are they to be assessed? There is no simple, “right” answer to questions of sustainable development – instead, there is a thoughtful, well-researched response that recognizes the concerns of stakeholders, the conflicting priorities and the economic, legal and social constraints of a design as well as its environmental legacy. How can students be introduced to this complexity and equipped to assess the viability of designs that claim to be sustainable? The aim of the method described here is not to define a single metric of index of sustainability; rather it is to improve the quality of discussion by providing a reasoning-path and guided access to relevant data [3].

“Wealth” is a generic term for all that we value. Global or national “wealth” can be seen as the sum of three components: the net manufactured capital, the net human capital and the net natural capital [4]. Sustainable development is as a development that takes in account the evolution of the three capitals, and aims at the increase of all of them. Examination of many articulations of sustainable development suggests the following picture. Each articulation has a motivating target that we will refer to as its “Prime Objective”. Each involves a set of Stakeholders. In assessing the sustainability of project the first step is to identify these: if the Prime Objective is not achievable or major Stakeholders are left dissatisfied, the project is unlikely to be sustainable. Further examination suggests that the central issues might be grouped under the six broad headings:

- Materials and Manufacture: supply-chain risk, life-cycle demands and recycle potential.
- Design: product function, performance and safety.
- Environment: energy efficiency, resource conservation, preserving clean air, water and land.
- Regulation: awareness of, and compliance with, National and International Agreements, Legislation, Directives, Restrictions and Agreements.
- Society: individual health, education, shelter, employment, equity and happiness.
- Economics: the cost of the project, and the benefits that it might provide.

This suggests the following way of analysing articulations of sustainable development. It has 5 steps (Figure 2). The first is a statement of Prime Objective, its scale and time envisage to achieve it (Step 1). Stakeholders are identified and their concerns listed (Step 2). These concerns are mapped onto a Fact-Finding search (Step 3) assembling data relevant to each of the headings listed above. This provides the background for a debate or discussion of the impact of these facts on Human, Natural and Manufactured capital (Step 4). The analysis ends with reflection on possible priority changes (Step 5). The first three steps are objective and deterministic; the last two are subjective, and therefore open to debate and creative thinking.

The methodology is applied during the course and it is articulated in order to facilitate discussion and debate about the interim and final results at class with stakeholders, faculty and other students. See figure 3 and table 1.

Table 1 shows de distribution of the five step methodology during the 12 weeks of the course. The table schedules the introduction of sustainable design strategies, the work related to the project that is realized in the classroom, the task to fulfil each week and finally the outcomes expected after the task are performed.

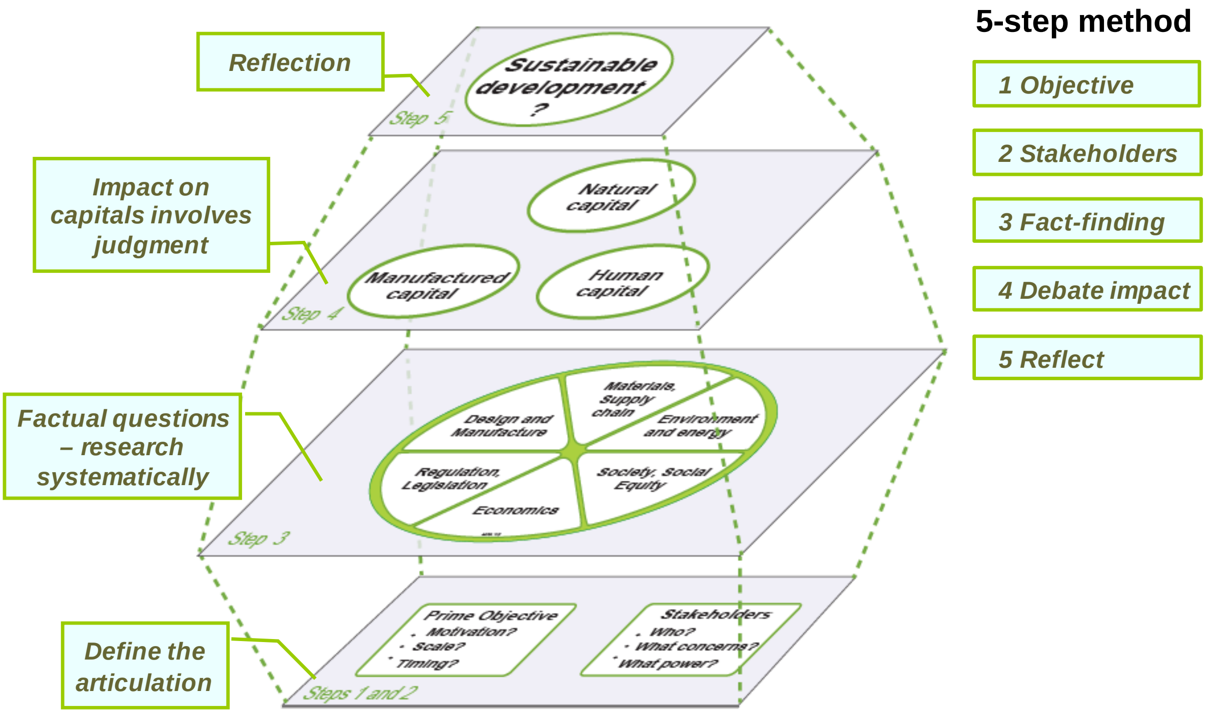

Figure 2. Methodology applied at Sustainable Design of Products and services course [3].

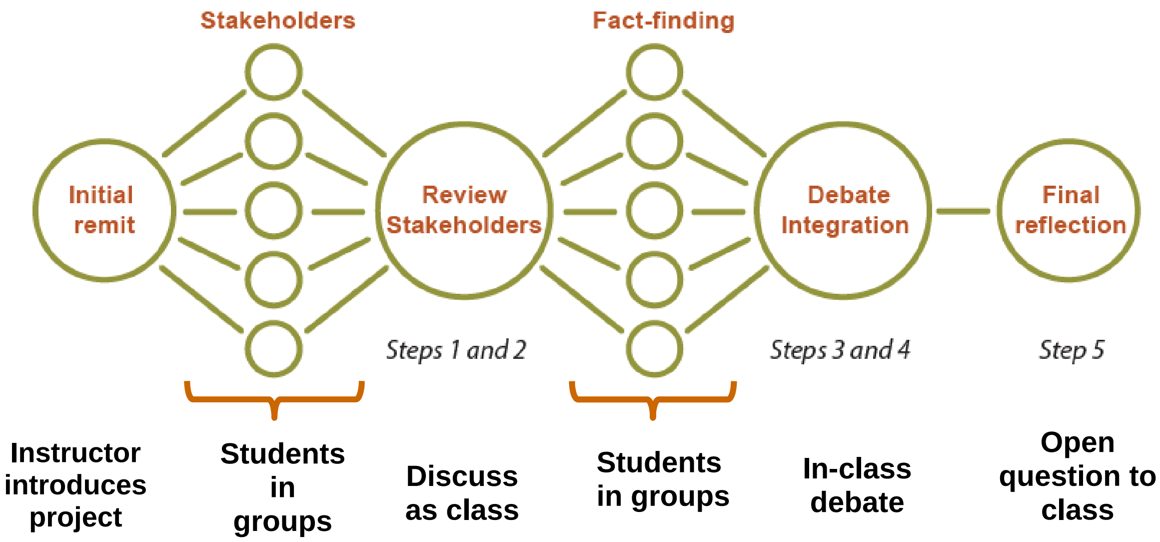

Figure 3. Articulation of the methodology facilitating discussion and debate [3].

To help with the fact finding step the sustainability database have been jointly designed with Granta Design [6]. The CES EduPack Sustainability Database is designed to support the teaching of sustainability at all levels of study. The database consists of seven interlinked data-tables. They provide the data needed for engineering design and for the eco-audit of products. The Sustainability Database allows materials to be traced back to their countries of origin and enables exploration of possible supply constraints. The data includes relevant legislation and regulations that bear on the use and disposal of materials. The information on price allows cost comparison of alternative design choices. Finally, the database allows the investigation of the economic, environmental and social profiles of the countries from which materials are sourced or in which manufacturing takes place. (Figure 4).

Table 1. Distribution in time of the methodology

WEEK	Strategies	Project	Tasks	Outcome
W1		Sustainable Design Project Methodology	Grouping + Project selection	
W2	Eco-design	Presentation of Campus Lab CE projects		Project Selection
W3		Grand objective	Discuss the grand Objective	Definition of the Grand Objective
W4	Cradle to cradle + Biomimicry	Stakeholders	Stakeholders Definition and strategy for their assessment	Definition stakeholders and stakeholders analysis strategy
W5		CES SUST. DB	Discuss Stakeholders	Stakeholder analysis
W6	Product-Service systems		Fact finding with CES-SUST DB or other sources	
W7	Social design		Fact finding with CES-SUST DB or other sources	
W8		Fact finding	Discuss fact finding	Fact Finding analysis
W9	Design for sustainable behaviour		Integration: Grand Objective + Stakeholders analysis + Fact finding	
W10		Integration > Sustainability analysis	Discuss integration	Integration > Sustainability analysis
W11		Alternatives and Redesign proposals	Discuss alternatives / Prepare defence of the project	Sustainable analysis and alternatives.
W12		Project Presentations	Project defence	Sustainable design report and presentation.

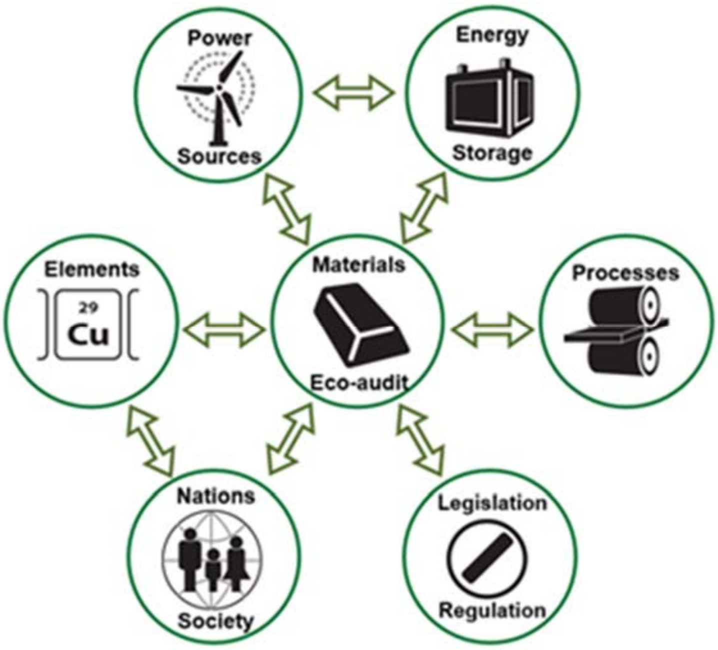

Figure 4. Interlinked data-tables of CES EduPack Sustainability Database tool [3].

The 5-step method and the SUSTAINABILITY database described here are contributions towards the difficult task of introducing students to the multi-dimensional aspects of Sustainable Development. It can be used for individual or for group projects. As a group activity, the role of a stakeholder and the responsibility for one fact-finding task can be assigned to each member of the group, the individuals research their assignation and report back to the group as a whole. This is then followed by a group “debate” seeking consensus on the impact of each of the fact-finding searches on the three capitals. The analysis as whole has a purpose and conclusions: while the underlying problem may be complex, it is important to report the result in a simple manner, making them accessible to non-experts.

At the end of the course, students were asked to give their opinion about the teaching method, the tools and their learning progress. The students appreciated the methodology as a holistic and practical approach to exploring sustainability. They commented that it gives guidance and focus while tackling the complexity of the task. They greatly appreciated the continuous feed-back from the teachers after each phase.

4 CONCLUSIONS

This paper has introduced a specific course in Sustainable Design of Products and Services (5 ECTS) at Master level at UPC Barcelona Tech. The author highlights that using community oriented and constructive learning approaches [3], where students work most of the time in real projects proposed by companies is crucial for sustainability education in general and specially in Sustainable Design education. Moreover, the five steps methodology here introduced, facilitates the sustainable holistic and systematic analysis of engineering projects where materials are relevant.

5 ACKNOWLEDGMENTS

We would like to thank the students, faculty and stakeholders that have participated in our experience.

ABSTRACT

One of the core and fundamental principles of sustainable development is responsible consuming of natural resources in order to maintain and better to increase them for future generations.The implementation of this principle is not possible without formation of a special world outlook of each member of society - the mindset of responsibility for the expenditure of resources and conditions regulating the use of resources.

Transformation of modern society from industrial into knowledge-based society requires a substantial increase of the role of the universities because they are just those organizations where the knowledge is gathered and disseminated. Today it is more common for universities to focus their efforts on developing competences rather than mindsets of future engineers. Apart of other considerations, another important issue is proposed for discussion in this article: a need to form/change students' mindsets, a need to develop specific learning environments at HEIs.

INTRODUCTION

Currently, global environmental challenges in conjunction with the issues of social responsibility are recognized as extremely important for all mankind. The search for ways to solve them has led to the development of the concept of sustainable

[1] Corresponding Author
K.K. Zaitseva
kkzaitseva@gmail.com

development in the 1980s and then to the first steps towards its implementation. The meaning of the concept of sustainable development is to identify the prerequisites and conditions for harmonizing socio-economic and environmental development and the lifestyle of every person on our planet. According to this concept, people must satisfy their needs in such a way that fundamental measures of the biosphere processes established over the millions of years are not violated and life of the next generations is not jeopardized [1]. In general, it is assumed that sustainable development should be characterized by the economic efficiency, biosphere compatibility, social justice, and comprehensive security through the harmonious development of the personality, society and nation as well as through the well-considered interaction with the nature [2].

On September 25, 2015, the States Members of the United Nations adopted the Agenda for Sustainable Development until 2030. It contains a number of goals aimed at eradicating poverty, conserving resources of the planet, and ensuring well-being for all. Each of the 17 Goals contains a number of indicators to be achieved by 2030. To achieve the Goals in the field of sustainable development, shared efforts of the governments, private sector, and civil society are needed.

Education is recognized as the most important mechanism for ensuring sustainable social and economic and spiritual (intellectual) development. This statement is also emphasized in the materials of the World Summit on Sustainable Development (Johannesburg, 2002). The key role in achieving the goals of sustainable development has to be played by the education system, which is called "a decisive factor for changes" in many UN documents. The wide recognition of the education and closely related upbringing and enlightenment as a decisive factor has made it necessary not only to consider the main issues related to the ecology and social responsibility in the process of training of engineers, but also foster the sustainability mindset of the students.

1 SUSTAINABILITY MINDSET

Currently, the world community is paying even more attention to sustainable development of our society: moderate consumption, greening and environmentalization of professional activities, responsible resource management, and other aspects that affect nature and society as a whole, as well as the ability to conserve resources for future generations. Considering of sustainable development principles is an integral part of training specialists in the field of engineering and technology. Graduates should build their professional activities in accordance with ethical, social, environmental standards, be responsible for the technical decisions they make, be able to forecast and reduce/prevent damage from the technologies they develop. The modern educational process requires adjustments in order to introduce the principles of sustainable development into the training process of engineers.

One of the core and fundamental principles of sustainable development is responsible consuming of natural resources in order to maintain and better to increase them for future generations. The implementation of this principle is not possible without formation of a special world outlook of each member of society - the mindset of responsibility for the expenditure of resources and conditions regulating the use of resources. Essentially, it involves social responsibility of each member of our society and communities at large (companies, enterprises, public organizations and others). This personal and corporate responsibility includes social consequences of all their activities and all kinds of their decisions concerning not only consuming exhaustible resources and resource saving, but also measures taken to create conditions necessary for this [3,4]. It is not a coincidence that that in the modern world exist and develop such trends as Responsible Research and Innovations, Responsible Industry, Technology Assessment, etc [5].

We can assume that an integrating condition for the realization of any of these trends is not only the formation of the competences of each person (specialist), participating in the decision-making process. It is important to manage development of sustainability mindset and social responsibility competence. These conditions cannot be met without active and decisive contribution of the education system at all stages. New models for sustainable education must be aimed at changing the mindsets of future generations beginning at an early age then fostered through formal education at undergraduate, graduate and professional levels.

To the credit of modern Russian engineering education, it is worth mentioning that training of socially responsible graduates became a notable trend. This ongoing trend is enhanced and supported by the requirements of Federal State Educational Standards, real academic activities within development and implementation of educational programs, curriculum requirements of several courses and disciplines, and, rarely, in scientific research. The process of developing competences among future graduates is realized along a study program and requires from students acquisition of fundamental knowledge and skills to be applied in practice. Usually it implies to provide ordinary and well-known conditions: qualified scientific and pedagogical staff, modern facilities, good connections with employers (cooperation with industry). To form any outlook in general, in addition to the above conditions, it is necessary to create a specific environment that forms the appropriate mindset of students.

2 SPECIFIC ENVIRONMENT AT UNIVERSITIES

Engineering influences directly the quality of life of the mankind; therefore, the actions of engineers require honesty, impartiality, justice, and efficiency. Their actions have to be aims at health protection, safety, and wellbeing of people. Fostering a socially-oriented mindset and behavior of future engineers requires from the educational organizations and educational process to implement adjustments in order to introduce the principles of sustainable development into the training process of engineers.

Analysis of the current state of implementation of the concept of sustainable development in the system of higher professional education shows that the most common approach is the introduction of a number of new disciplines in the field of sustainable development in the curriculum, particularly ecology, resourceefficiency management, etc. [6,7] However, those measures are not enough to develop a culture of sustainable development among the academic and management staff and students. This paper introduces a new holistic approach that aims to create a specific environment within a university for fostering sustainable development and social responsibility mindset that allows future engineers to take managerial, project, economic, social, and political decisions that are adequate to the crisis situations and trends faced in all spheres of life of the nation and the world community at large.

Despite the application of competence-based approach to the process of educational programs' development, the contents of the programs and teaching and learning methods used, as a rule, do not allow fostering future specialists' skills, attitudes and knowledge on a level needed for winning in a competitive battle. At this, it is necessary to mention that representatives of industry confirm a good level of basic knowledge and theoretical background on certain disciplines. However, they point out as an evident drawback a low level of key competences' formation (professional skills and soft skills), as well as a low level of practical skills needed for solving real engineering tasks and problems.

Introduction of the competence-based approach to the designing of educational programs is a necessary, but not sufficient condition required for guarantee the expected level of future specialists' competences of social responsibility within the educational process. The pivotal factors ensuring the formation of required competences within the educational process are the teaching and learning methods and conditions for their implementation (including the potential and qualification of faculty) and the specific university environments that support fostering of competences.

The analysis of world's best practices in identifying and developing specific learning environments allowed to select most challenging and vital types of environments listed below:

1. Environment for sustainable development, including
    a. Ecological (greening) environment
    b. Social responsibility environment
    c. Lean production environment
2. Creative environment
3. Entrepreneurial environment
4. Project based learning environment.

As mentioned above today it is more common for universities to focus their efforts on developing competences rather than mindsets of future engineers. Apart of other considerations a necessary condition to form/change students' mindsets is that higher education institutions need to develop specific learning environments, as shown in the Fig. 1 [8].

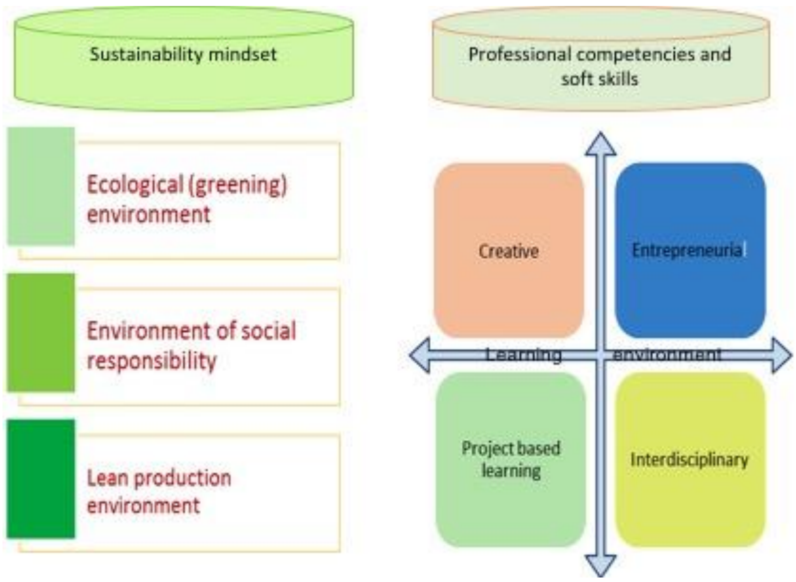

Fig. 1. Specific learning environment

Specific environments such as "ecological environment", "environment forming responsibility", "creative (innovative) environment", etc., create the basis for the development of relevant competencies at university, both for students and teachers, and for managerial staff. Orientation of the university on purposeful formation of specific environments will allow in a more successful way and in a shorter period of time to implement qualified training of graduates in the field of engineering and technology that meet the requirements of the labor market and the modern society as a whole.

The paper presents an ongoing reserach at Tomsk Polytechnic University with the support of Association for Engineering Education of Russia. The key direction of the research is changing the paradigm of thinking and professional activity of the future engineer, fostering new students' mindset, aimed at understanding the responsibility for resource endowment of the next generations, changing consumption patterns, forming a new lifestyle. The priority is given to the development of tools for the implementation of (scientific, theoretical, informative, pedagogical, technological, organizational) aspects of sustainable development concept in the system of training students in the field of engineering and technology.

The main objective of the research is the development and pilot testing of methods, tools and actions for creating specific university environments that contribute to fostering sustainable development and social responsibility mindset.

We assume that creation of such university environment will allow to transform the mindset of all stakeholders involved in the educational process (students, academic staff and administration of the university). It will ensure more sustainable development of students' competences, facilitate their employability and will become one of the most important steps how the educational process could respond the big challenges.

The toolkit proposed for the development is universal in nature and can be applied in different types of universities (technical, classical, medical, etc.) in order to promote creation of specific environments of any type. The complex of actions for the development of specific environments can be adapted to the needs of the country, region and the university itself. The actions should be continuously pursued, thus contributing not only to the initial creation of the environment, but also to its maintenance and development.

3 SUMMARY AND ACKNOWLEDGMENTS

Revealing the new paradigm of education in the interests of sustainable development, it is necessary to point out the main aspect of the orientation of any moral teaching. It involves formation of a new mindset. In the available nowadays research studies this issue is not highlighted enough when talking about training of future engineers. Nevertheless, in our opinion, mindset development is an essential and fundamental element in the structure of professional engineering activity. Despite the recognition of the importance of reforming education systems for ensuring sustainable development, the efforts are not successful enough. This is partly due to the fact that pedagogical traditions are based on the transfer of existing knowledge, the reproduction of real connections and attitudes reflected in the public consciousness. The future is always more or less uncertain. This fact determines, in essence, the establishment of fundamentally new pedagogical and management tasks related to the formation of a sustainable development mindset.

The necessary fundamental basis needed by every graduate for systemic and holistic solving of real-life problems is fostered through the prism of professional competency. A universal, creative, developing personality of a future professional can be formed only if there is a continuous pedagogical process and each stage of it is based on integrated principles and methods and has a core aim – professional competency of an engineer, who will be able to ensure sustainable development.

ISMEP-Supmeca: an example of recognition of training on sustainable development and social responsibility through the awarding of the new French “Label DD&RS”

Antoine Lanthony

Alexis François

Gérald Majou de La Débutrie

Clara Doly-Tacconi

ABSTRACT

In December 2016, ISMEP-Supmeca, a French public engineering school, obtained a SD&SR (Sustainable Development and Social Responsibility) label for a period of 4 years.

Launched in France in 2015, this "SD&SR label” (“label DD&RS” in French) is the result of the work of many stakeholders: higher education institutions, ministries, associations... Carried out by CIRSES (French higher education SD&SR collective), it is organized around five themes and allows to:

- Promote the best SD&SR initiatives of French higher education and research institutions,
- Upgrade skills within a group of committed institutions.

ISMEP-Supmeca chose to respond to this labeling approach. In this paper, we will first focus on the SD&SR label. Then, we will present the approach of ISMEP-

Supmeca and detail the strategic variables of the education axis of the label through the sustainable development education policy developed at ISMEP-Supméca:

- Train and prepare engineering students for tomorrow's issues, problems and jobs, emphasizing the initiatives and opportunities presented by SD&SR,
- Continue to gradually integrate SD&SR as tied approach, knowledge and skills in all modules, projects and courses offered in the curriculum.

We will conclude with a focus on one specific action undertaken at ISMEP-Supmeca, the “SD&SR days”.

Conference Key Areas: Sustainability and Engineering Education, Ethics in Engineering Education, Engineering Skills

Keywords: Sustainable development and social responsibility, Engineering Education, Labeling

INTRODUCTION

ISMEP-Supmeca is a human-sized French public engineering school, located in a rapid-changing part in the north of the Great Paris area and engaged in sustainable development and social responsibility policies for many years.

In 2016, the institution decided to engage into the recognition of this engagement and the result was obtained quickly: ISMEP-Supmeca was awarded a SD&SR (Sustainable Development and Social Responsibility) label for a period of 4 years.

In the first part, we will present this "SD&SR label” (“label DD&RS” in French), launched in 2015 and the result of the work of many stakeholders: higher education institutions, ministries, associations...

Then, in the second part, we will present ISMEP-Supmeca and especially focus on the approach of the institution towards SD&SR in general and the education axis in particular, with references to the specific SD&SR education policy and to the so-called “SD&SR days”.

1 THE FRENCH SD&SR LABELING SYSTEM

1.1 Some words and facts about the French SD&SR label and its operator

France has a higher education system involving two main kinds of institutions providing education: universities and Grandes Ecoles (engineering schools and business schools). It has also bodies playing a great role like the Conference of Grandes Ecoles and the Conference of University Presidents. Finally, it has a strong accreditation history, with, for example, the CTI (Commission des Titres d’Ingénieur), engineering accreditation institution, which introduced high-level standards and is now paying a lot of attention to topics like SD&SR.

Created and launched in France in 2015, the "SD&SR label” (label DD&RS in French) labeling system is the result of the collective work of a dozen universities and so-called “Grandes Ecoles”, the Conference of Grandes Ecoles, the Conference of University Presidents, the Ministry in charge of Sustainable Development, the Ministry in charge of Higher Education and the French Network of Students for Sustainable Development.

It meets the implicit demand of a growing number of institutions developing initiatives and it is fully in line with the article #55 of the first so-called “Grenelle environnement” (open multi-party debate in France that brings together representatives of national and local government and organizations).

The label, based on a self-assessment tool “SD&SR framework”, is carried out by CIRSES (French acronym for Collective for the Integration of Corporate Social Responsibility and Sustainable Development in Higher Education), the latter being an association with three main objectives:

- To support the persons in charge of the SD&SR mission in the higher education institutions,
- To contribute to the influence of the SD&SR initiatives of the higher education institutions,
- To be the reference in terms of SD&SR practices in the French higher education and research area.

Concretely, the SD&SR label is accompanying the objectives presented above. Its main aims are to:

- Promote nationally and internationally the best SD&SR initiatives of the French higher education and research institutions,
- Upgrade skills in the framework of a group of committed institutions.

Labelling sessions took place, under a process and with first results presented hereafter.

1.2 How it works and first results

Two labelling sessions have already taken place since the label began to work: the 2015-2016 winter session (from October 2015 to May 2016) and the 2016 summer session (from March 2016 to December 2016). Each session starts with the application period, followed by the assessment by auditors, then by a direct audit and is closed by a meeting of the labelling committee, officially awarding or not the label.

The whole evaluation process is based on a SD&SR assessment grid organised around 5 main axes:

- 1. Strategy and governance,
- 2. Education,
- 3. Research,
- 4. Environmental management,
- 5. Social policy and territorial rooting.

These axes and more generally the grid are referring to the axes defined in the so-called Green plan constructed by the stakeholders of the higher education and research area and already tested with success by more than 100 institutions since 2012.

Each institution aiming to apply has to provide a self-assessment of its SD&SR policy by filling in the assessment grid, each axis containing sub-topics and then each sub-topic containing sub-items. This has to be completed by supporting documents.

The first assessment, done on these documents, is completed by an assessment meeting with representatives of the applicant institution. Both parts of the assessment process result in awarding the label or not.

A total of fourteen institutions was awarded during the two first labelling sessions: ten engineering schools, two business schools and two universities. More institutions have already applied, will apply and will be awarded the label in the coming months.

ISMEP-Supmeca is one of these first fourteen institutions, which responded to the second application wave at a moment corresponding to its wish to see its actions recognised. Hereafter we will focus on the institution SD&SR actions and policy.

2 ISMEP-SUPMECA: AN INSTITUTION WITH A RECOGNIZED SD&SR POLICY

2.1 From the first actions to the SD&SR label award

ISMEP-Supmeca is French public engineering school, giving to its students a three-year engineering education (1/3 of internships; 1/3 of projects and experimentation; 1/3 of courses and supervised practical work), making them specialists in modelling, conception and production systems, who will mainly join large industrial companies. The school hosts globally around 600 students on these three levels (for example, in 2016-2017: 490 students in a classic engineer curricula, 140 students in an apprenticeship engineer curricula and 16 students in a specialized or advanced master on lean management), making in a human-sized school. It also has a global staff of around 200 people (permanent and non-permanent).

ISMEP-Supmeca is located in Saint-Ouen, in Seine-Saint-Denis department, i.e. in a rapid-changing part of the north of the Great Paris area. Being one of the only two public engineering schools of this department, ISMEP-Supmeca also faces challenges due to its location in a dense residential and post-industrial urban area.

Taking all these aspects into account, ISMEP-Supmeca engaged step-by-step into a real SD&SR approach in 2010, the SD&SR label obtained being the concretization of both the engagement and the strategy.

The first actions in favor of the development of a SD&SR were taken in 2010 and were from the beginning placed in the larger framework of a real strategy. Indeed, a SD&SR officer started working in June 2010 and this was followed by the first steering committee until the design and writing of the first SD&SR charger of the institution in November 2010.

From that date and under the supervision of different persons in charge of the management of the SD&SR policy (in addition to their initial tasks at ISMEP-Supmeca), this policy grew, with many particular actions. We can quote among others the following ones:

- Development of an apiary,
- Writing of a monthly SD&SR info-flash,
- Provision of electrical bikes to ISMEP-Supmeca staff members,
- Student association doing remedial courses for children from Saint-Ouen and neighbouring municipalities,
- Formalisation and co-building of the professional training for the staff,
- Diagnostic of psycho-social risks.

All these actions are integrated into five axes defined previously in this article and also integrated into the SD&SR strategy of the institution. Revised in 2016, this strategy defines two main SD&SR wishes for ISMEP-Supmeca:

- Acting with students, who will be the main SD&SR vectors in the context of their future professional life,

- Training all the students so that they can be ready and able to make an energy balance, a carbon assessment and a lifecycle analysis.

The secondary wishes of the school defined in the SD&SR strategy are the following:

- Promote SD&SR through concrete actions,
- Use the family size of the school in order to conduct projects involving staff, students and graduates,
- Be a pioneer in its territory and be more open towards its territory.

This global SD&SR strategy is completed by a specific SD&SR educational strategy, linked to the “Education” axis of the Green plan or SD&SR label assessment grid.

Beyond the actions and the formalisation into the strategy, there is the third very important point: the involvement of the stakeholders. There is a core group of people, both staff and students, who make SD&SR a reality at ISMEP-Supmeca. Several student associations (Soutien Scolaire Supmeca, involved in remedial courses, Ecostudent or New Defi) and a small group of key staff members are very involved in these issues, being pro-active and available.

After six years of actions, it was decided to try to gain a recognition for the work done and to apply for the SD&SR label in order to receive this recognition.

As presented in figure 1 hereafter, the institution was assessed 3 out of 5 in four of five axes (Strategy and governance, Education, Environmental management, Social policy and territorial rooting), and received 2 out of 5 in the Research axis, which is, according to CIRSES, the most difficult to get a good mark.

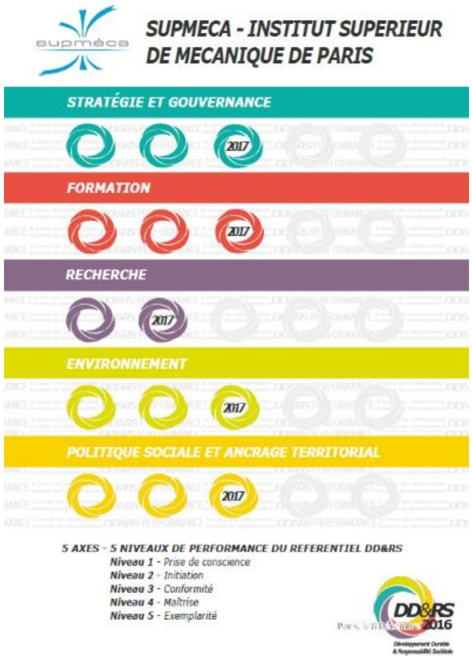

Fig. 1. Performance summary of ISMEP-Supmeca at the SD&SR (“DD&RS” in French) labelling session

The awarding of the label for a period of four years (with mid-period self-assessment to provide) and the 3 out of 5 marks obtained on four axes reflect the work done and could have been even better with a better formalisation of the actions, especially in the Education axis, where more and more is being done.

2.2 Education first: responsible engineers for the twenty-first century

The specific SD&SR educational strategy developed at ISMEP-Supmeca is linked to the "Education" axis of the Green plan or SD&SR label assessment grid and makes the integration of SD&SR possible at different levels and different moments of the curricula, in order to make the future engineers responsible engineers able to work and behave like ducks in the water in the twenty-first century. The main elements resulting from this strategy and present in the curricula are:

- Integration of SD&SR issues into the internship reports (4-week operator internship in the first year, 18-week assistant-engineer internship in the second year, 24-week engineer internship in the third year),
- Integration of SD&SR issues in the framework of problem- and project-based pedagogy: PRIM module (Mechanical Engineering project / 26 half-days per student in the first year), PLACIS project (5-month project for incoming students in the second year), Design office project (25 half-days per student in the second year), Synthesis project (48 half-days per student in the third year), PLACIS project (48 additional half-days to the synthesis project in the third year),
- Core course on Ecological footprint of the systems / 24-hour course for second-year students (20 hours for apprenticeship students) corresponding to 2 ECTS,
- Elective course on Ecodesign of Systems / 32-hour course in the second year corresponding to 2 ECTS,
- SD&SR days, developed in the next part of this paper.

This list can be divided into four parts: internships, projects, classical courses and special days. The projects are very interested here as they already share common values with SD&SR, especially the PRIM module and the PLACIS projects.

PRIM module is a full multidisciplinary problem-based module using topics like wind turbine conception in order to teach a bench of mechanical courses and associated skills.

PLACIS projects are multidisciplinary and systems-oriented projects, most of them being multi-semester, international, industrial and addressing direct SD&SR issues, like electrical and hybrid vehicles, biomimicry, eco-planes of the future… One of the important added-value of these projects is that they teach students how to work collaboratively, at-a-distance, on real long-term projects.

Also, the two classical courses presented above lead to specific SD&SR skills and competencies, but they are not the only ones. Courses linked to systems engineering and systems analysis or linked to materials also lead to SD&SR skills. For this reason, responding to a demand from both the CTI and the SD&SR label auditors, SD&SR issues are being clarified or introduced in a growing number of courses and under new formats, which tend to be successful, as proven by the SD&SR days presented in-depth at a recent congress in France [1] and briefly presented hereafter.

2.3 The SD&SR days: an example of training initiative

There are two SD&SR days: a half SD&SR day for first-year students and a SD&SR day for third-year students. Set up for several years, the DD & RS days were initially in a classic format of conferences by experts in topics like wind energy or cooperative companies. These conferences met limited success and students asked for an evolution towards a less passive format, both agreed and pushed by the staff.

These days have therefore evolved into a participatory format allowing to better capture their students' attention, as well as stimulating imagination and exchanges. This evolution was carried out in a progressive way: a transition to a participative format for the half-day for first-year students in 2015-2016, and then, regarding the success, a transition to the same participative format for both days in 2016-2017.

Concretely, the half-day for first-year students takes place in the following way: the students, divided into two rooms, work in groups by brainstorming method and then perform a pooling and restitution by room before one or more professional(s), who comment on the renditions and then present their experiences. For example, in 2015-2016 and 2016-2017, the objectives of the students were to: 1. define the SD&SR and imagine themes, missions, objectives, skills, interlocutors, problems of a SD&SR manager in a SME or a large group; 2. Imagine interactions and constraints related to the SD&SR of an engineer when he is in office.

The SD&SR day for students of the third year has also been participatory since 2016-2017: the morning is devoted to brainstorming and pooling; the afternoon to presentations and interventions. This day proposed for its first edition a prospective reflection around seven themes (passenger and freight transport, management of nuisances, well-being at work, circular economy ...), each of which treated by two groups, which later pooled and presented their results in the form of mental maps.

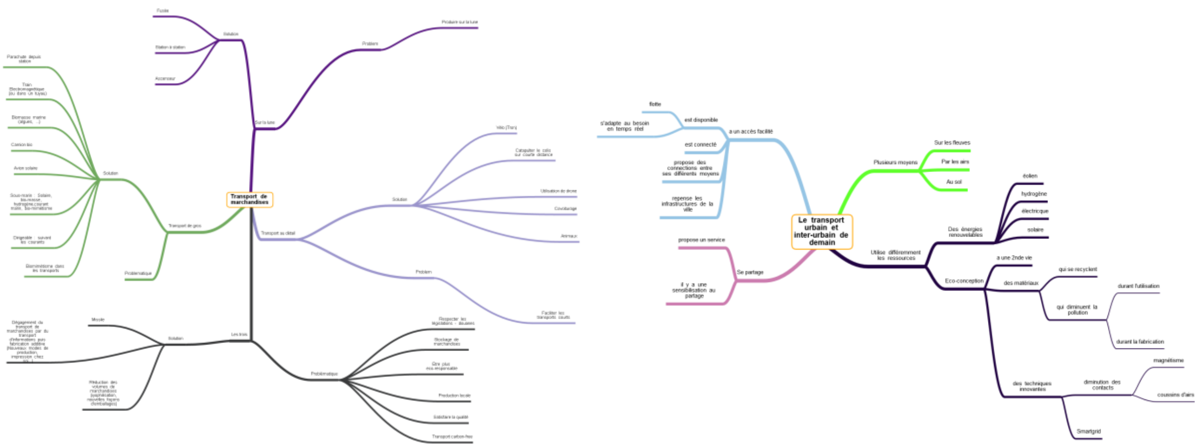

Fig. 2. Examples of mental maps produced by the students (in order to see the diversity of paths followed)

Not only the SD&SR topics were an added value for the students, but also the tools: both mental map and brainstorming were new for most of them. Even if not fully appropriately used by everyone, these tools brought positive results about their use by the persons attending these days, including professional ones.

One very positive point is that professionals highly rated their involvement in these days, but also students highly valuated the participation of the professionals, who had the opportunity to present concrete experiences and engage the debate on some issues. High-rank persons from Kering, Alstom and SNCF Reseau already participated, the two latter ones based in Seine-Saint-Denis department and enforcing the local rooting of ISMEP-Supmeca.

The feedback to these events is very positive. Satisfaction surveys (questions on the principle of the day, the program, the participative format, the interventions, and the presentations for third year students) conducted after each event indicate for example that first-year students endorse very much the participative format and third-year students also attach great importance to the presence of an enthusiastic external professional commentator. If we convert the evaluations to a score of 20, for the academic year 2016-2017, the half-day for first-year students was rated 14.7/20 and the day for third-year students was rated 13.9/20.

There are three categories of comments enclosed to the answers to the surveys:

- The positive ones, being the large majority, for example:
  - "extremely interesting, to be renewed absolutely for future promotions, this day reinforced me in the idea of wanting to work in SD&SR",
  - “format more interesting than the usual conferences",
  - "well to do a brainstorming",
  - “Interaction with professional stakeholders: ++".
- The ones asking for changes or expressing proposals, like the following ones:
  - "to be done in September or October",
  - "more actions are needed: garbage collection in parks".
- The sceptical or negative ones, like the following ones:
  - "concept rehashed for nearly 20 years",
  - "we are sensitized on themes on which we have no influence".

We took very much into account the two last categories of comments. For example, these events will take place earlier in the calendar from 2017-2018. Also, we think that resignation or criticism are linked to the fact that for some students, SD&SR is reduced to its environmental aspect. In order to counter that, we will focus more on economic and societal issues in the monthly SD&SR info-flashes. We will also try to make sure that as many students as possible are aware of the possibility, as engineers, of influencing a certain number of choices and conducting a systemic reflection integrating all the SD&SR parameters, despite various constraints which they will confront.

3 GOING FURTHER

Empowering the students and making them aware of the possibilities and limits they will have in their jobs and lives join the main SD&SR wishes of ISMEP-Supmeca. Linking SD&SR with project-based learning is already done and linking it with entrepreneurship is on the to-do list of of the institution, the latter aiming to go further in terms of actions and formalization.

Moreover, following both the continuous improvement approach promoted by CIRSES and the need for transdisciplinary approaches, more and more courses will be featured with references to SD&SR issues will lead to the gain of SD&SR-linked skills. The ongoing improvement and lifting of the syllabus of the institution will fasten this process, which will also need to be discussed with all the teachers involved, in order to enjoy the best understanding of the place of SD&SR issues in the different courses and taking into account the main learning outcomes and pedagogy approaches of these courses.

ABSTRACT

As one of key drivers to solve real-life problems in practice of sustainable innovation, creativity has been argued as an important skill that engineering graduates have to master. This paper will mainly focus on 1) how to understand the concept of creativity and its relevance with sustainability in engineering design, and 2) as the educators, how we can provide basic conditions to recognise, develop, and assess creativity among engineering design students. The two focuses will further drive us to discuss a case of an education program of Medialogy at Aalborg University (AAU) in Denmark. Briefly, this paper contributes to bringing together with areas of creativity, engineering design, and engineering education, which also indicate that it has both theoretical and practical significances.

Conference Key Areas: Sustainability and Engineering Education, Engineering Skills

Keywords: creativity, engineering design, engineering education, sustainability, creativity assessment

INTRODUCTION

Recently, creativity has become a crucial issue for human-resource management in both academic research and industry. It is increasingly recognised that creativity and innovation are required to deal with changing circumstances in education and society as a whole [1]. So, the universities are increasingly expected to provide more opportunities that foster and nurture creativity in engineering students. Engineering students need creative minds to meet the advancing goal of engineering profession, design new products or systems and improve existing ones for the benefit of humankind [2]

The arguments that engineering design students require creativity also involve the consideration of developing sustainability [3]. In engineering design, it is necessary to add customers' requirements related to sustainability. Both the development of a product and making it sustainable requires the involvement of creativity into product design. So during the product lifecycle, the engineers must be able to be creative in all areas of the process. The creativity not only makes them more competitive than before but also favours more sustainability with innovation for possible solutions to many of the problems [4].

Following the above, this paper emphasises the necessity of developing creativity among engineering students and deepens the understanding of creativity and its assessment methods. This further implies us to show the plan of curriculum design in an educational program of Mediaology at Aalborg University (AAU) in Denmark. Therefore, this paper not only contributes to a theoretical bridging creativity and engineering design education in one framework, but also provide practical implications to educators for recognising and assessing creativity among engineering design students.

1 WHAT IS CREATIVITY?

The creativity has many perspectives of seeing. Creativity can be defined simply as a generation of a new and useful idea [5], [6]. In other words, Creativity is the conceptualization, the schematization and the execution of ideas [7], [8].

Therefore, the meaning is subjective to be measured at different cultures and backgrounds. According to Zhou [9], creativity has to see in an integral mode, as the integration of knowledge and skills. It could be effective to assess people to selection, management or classification purposes. The interaction between persons could see at the interpersonal, the group, and the socio-cultural level. Both individual and group can produce a tangible product, material or immaterial that is useful according to with the social contexts [10], [11]. Consequently, creativity could recognise by the people, the product, the process and the environment. That approach to assessing creativity is known as the 4P's of creativity, which means Person, Process, Product and Place.

2 CREATIVITY AND SUSTIANABILITY IN ENGINEERING DESIGN

In engineering design, creativity has its significances of developing sustainability. A new idea always has to be tested or use to be a real "idea" that is also useful. In a broad sense, we may view creativity as a pathway to develop sustainability. While sustainability refers to the design of human and industrial systems "to ensure that humankind's use of natural resources and cycles do not lead to diminished quality of life due either to losses in future economic opportunities or adverse impacts on social conditions, health and the environment"[12, p. 5315].

Furthermore, we can use the principles of precautionary and the prevention when to assess sustainability that also has effects on creativity. The precautionary principle is a strategy to address uncertainties in risk management [13]. This principle establishes that uncertainty determines the measures that must be taken to avoid damages to society and the environment. Therefore, engineers must take actions before damage can occur. Therefore, cautions include wider assumptions, recognise weaknesses and points where there is not knowledge, uncertainty, advantages and disadvantages, stakeholder recommendations, use of specialists, documents, and the real operating conditions. Also, engineers have to think of short- and long-term monitoring programs [14], [15]. The principle of prevention states that if the consequences and probability or occurrence of any activity is known, measures should be taken to avoid further damage to the environment or society.

According to Cucuzzella [4], the precautionary mode is typical of the stages of the formulation of the problem and involve reflection in action. The prevention mode is for stages involves technical knowledge while developing the solution of the problem. At the stage of a problem, the setting should appear requirements that include uncertainty. The way of the problem is addressed, and the different alternatives of presenting it are related to creativity. Furthermore, creativity promotes the search for various alternatives. The preventionary approach is oriented toward various action alternatives, reconstructing existing social and cultural elements; while the precautionary approach uses both instrumental models and critically constructed models. So the two principles have opposite effects on creativity in problem-solving and problem-setting contexts.

However, to Cucuzzella [4], also argued that the two principles of precaution and prevention coexist within a problem-solving and problem-setting model of thinking. That makes it possible to reveal at least four tensions that help to understand how creativity is impacted in the context of designing for sustainability. The four tensions are: (1) analogical/logical conceptualization, (2) epistemological/methodological uncertainty, (3) interpretive/analytic comparability, and (4) universal/contextual relevance of proposal. These four tensions comprise a system for judgment as they each address a major element of design thinking.

3 ASSESSING CREATIVITY IN ENGINEERING DESIGN EDUCATION

According to the literature [16], there is a great deal of controversy about the meaning of the word creativity, particularly in a university setting. It shows that some disciplines have been involved:

1) Psychology has focused on the individual’s creativity and tried to identify the cognitive capacities and traits of personality that make up a creative person.
2) Social psychology has studied the process of creativity as an interaction within a given context.
3) Sociology (and organisation theory) has emphasised creativity as an environmental process and studied efficient communication networks made up of prominent personalities with broad and deep knowledge.

Törnkvist [16] also argued it is important to recognise which approach mentioned in the above when we develop and assess students’ creativity in engineering education. For example, if one believes that creativity is constituted by a set of traits of personality only, testing for those traits of personality only, testing for those traits at entry level would seem to be a necessary and sufficient means of ensuring future creativity. If one believes that the social context has influences on creativity, as suggested by Amabile and Pillemer [17], creativity could be taught, learned, practised and developed, and everyone has potential to be more creative than before through positive influences of educational environments on developing creative ideas and learning methods of developing creativity. So, in educational methods based on collaboration, the assessing of creativity is view as a result of a process, at the end of an individual or group work.

In engineering design, assessing creativity has been focused on from a product perspective [18]–[21]. Creative engineering designers are those who can explore and scrutinise the available data or information and generate novel solutions to specific engineering problems or the production of a unique product are demanded in work places and markets [21]–[23]. The following four aspects of defining a creative product should be considered [23]

1) Relevance and effectiveness: the product solves the problem it was intended to solve.
2) Novelty: the product is original and ‘surprising’.
3) Elegance: the product is ‘beautiful’ or pleasing, and goes beyond a simple mechanical solution. And
4) Generalizability: the product is broadly applicable - it can be transferred to situations other than the present one and opens up perspectives for solving other problems.

Furthermore, as little engineering work is solitary, it is increasingly being recognised as a collaborative problem-solving process where is also the main context of creativity among engineers [23]. Also, ‘responsibility’ should be involved, which highlights the designers must be able and willing to think about their ethical liability for the consequences when the creative products are applied in practice [24]. For example, the relevance of sustainability with engineering design has been emphasised in this paper.

Also, to better assess creativity from the perspective of the product, observers have to review both the process explanation for the developing the product and the final product. There could involve many aspects, such as the problem formulation, user requirements and preliminary, and final specifications. Furthermore, the observers have to deal with accidental aspects (e.g., unintentional solutions). A student was tacitly explaining in a special session on a report facilitating the observation process.

4 DEVELOPING CREATIVITY IN ENGINEERING DESIGN EDUCATION

In the following, we take an example of the curriculum plan in a student programme of Medialogy at Aalborg University (AAU) in Denmark to show how engineering design education may provide necessary conditions for creativity. It should be noted here that AAU has a long tradition of an educational model of Problem-Based Learning (PBL). Students in Medialogy will have a ten-semester study period. Every semester, each student group should finish a project report which indicates their design processes and design products in solving real-life problems.

The Bachelor's degree in Medialogy at AAU begins with the students getting an insight into basic Information technology, Communication, New Media, Programming and the completion of a problem-oriented project. In the first year, the students in project teams analyse and solve a problem within the area Human-Computer Interaction. They draw up a problem formation and qualify a research question where they will be able to apply their knowledge and skills in mathematics, programming and interaction design. *Fig. 1* shows the detailed description of learning objectives of student projects.

Title: **Human-computer interaction**
15 ECT
Objectives: After completing the Project module, the student shall be able to demonstrate knowledge, skills and competencies in how design, develop and evaluate and artefact.
Knowledge • Describe new form of interaction with the real word, data sources, and/or physical/virtual models (understanding) • Explain how human computer confluence can enhance the foundations for future applications of societal value (understanding) • Explain the methods for planning and developing and IT application (understanding) • Explain the iterative nature of interaction design (understanding)
Skills • Applied the human center design approach in the contest of use, design, development and evaluation of a new interface (understanding) • Design, plan, organise and conduct user needs study of a target group (synthesis) • Analyse how a chosen target group interacts in a real world context of use with similar media products or artefacts and apply this to novel designs through, e.g., scenarios and storyboards, and later with early prototypes • Apply methods, tools and theories to allow people to explore and augment human interaction capabilities and awareness in action and interaction. • Synthesize technical requirements specifications as a basis for developing a media technology project • Design and implement a simple artefact based on fundamental object-oriented programming (COP) strategies, models and development environments (application) • Prepare and perform standarised testing of an artefact with the target user group (not a convenience sample) or domain experts and analyse and discuss the findings (application)
Competencies • Apply the gained experiences with project management to the future course of study (evaluation) • Evaluate the ethical perspective of engineering and science and discuss implications of a responsible professional practice (analysis) • Explain basic quantitative results with descriptive statistics in writing and in figures (application)

Fig. 1. Learning Objectives in Medialogy

So the students must create a model of the problem and include relevant concepts, theory and methods for analysis and assessment of possible sustainable solutions. As part of the solution, the students must develop an artefact, which has to be documented in the project report.

For example, The Intelligent Ashtray shown in *Fig. 2* is one of the students' projects in the 2nd semester. The overall theme of the semester is garbage in Denmark. The students first look at a lot of different areas to work their way towards finding a solvable problem in regards to garbage and dogged into which matters could be resolved. Then one group of students are very interested in issues of smokers. The issue is not merely that people throw the cigarette butts to irritate other persons, but rather another issue in finding places to dispose of it. Some people state that they do not recognise cigarette butts as litter, while others state that most ashtrays are full. Whatever the reason may be for not disposing of the cigarette butts correctly, the students decided to try and count this problem Based on the problem analysis. Finally, a problem formation was created by the students:

How do we motivate our primary group, the smokers, to reduce their littering of cigarette butts and in turn create awareness for our secondary group, the non-smokers, in the city of Aalborg?

This project aims to solve the problem formation with an interactive ashtray, with a design that would make it easy to spot. The ashtray has an info-screen, which seeks to change the user's perspectives in littering through information printed on-screen.

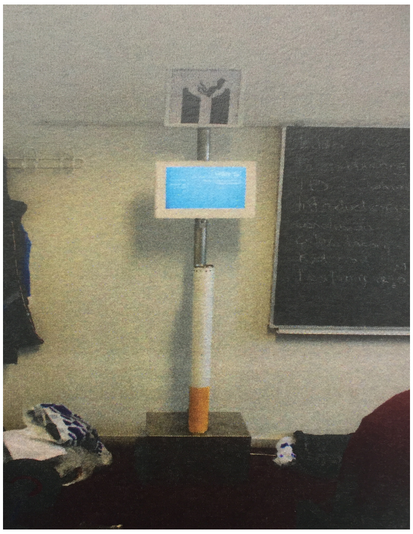

Fig. 2. The Intelligent Ashtray

The project includes a full implementation and product test. It showed, that "The Intelligent Astray" in the city of Aalborg had an impact on both the primary and the secondary target groups, in that it changed the motivations of the smokers to use the ashtray and made the non-smokers aware of the issues surrounding cigarette littering.

From the above case, we can learn that in Medialogy, sustainability has been an important element embedded in the curriculum design. Meanwhile, the product perspective creativity has been highlighted when the students are required to solve real-life problems; the criteria for assessing creativity discussed previously including relevance and effectiveness, novelty, elegance, and generalizability have also been encouraged to be reached among the students in the process of their design. Also, AAU is a supportive educational environment to develop creativity, as it has core principles such as group work, student-centered learning, and the shift from teaching to facilitation, which meets the requirements of fostering a creative learning atmosphere and students' active participation in creative activities.

5 CONCLUSIONS

This paper addresses the issues of developing creativity among engineering design students. These issues involve how to rethink what the concept of creativity means in the field of engineering design and its relevance with sustainability, and how to recognise and assess creativity among engineering design students. It is clear that only when educators have the strong awareness of developing creative teaching and learning, and when they can understand and recognise the needs and the particular characteristics of creativity in engineering design, the supportive curriculum design and educational environment can be accordingly developed. So a case of a student programme of Medialogy at AAU discussed may provide a practical example of how to integrate creativity into curriculums in engineering design education, which also provide implications for other engineering institutions around the world.

Transforming Engineering Education: DESIGN must be the Core

R. G. Hadgraft[1]
Director, Educational Innovation and Research
Faculty of Engineering and IT, University of Technology Sydney
Sydney, Australia
E-mail: http://roger.hadgraft@UTS.edu.au

ABSTRACT

There have been many reviews of engineering education over the last 15 years, yet most engineering curricula remain traditionally focused on the development of technical outcomes, with a small emphasis on design. This paper reviews many of the international reviews, to seek the common themes that need to be addressed. Examples of new curricula are provided. Although the design of new curricula is difficult enough, it is the implementation of change within our existing academic structures that is really the difficult problem to be solved.

Conference Key Areas: Curriculum Development, Quality Assurance and Accreditation, Skills and Engineering Education

Keywords: engineering education transformation, engineering curricula, project-based learning, graduate outcomes, accreditation

INTRODUCTION

There have been numerous international reviews calling for changes to engineering education [1-9]. The key recommendations are enlightening and complementary. However, the sense of urgency for change seems curiously absent, despite many such reports over the last 15 years.

This paper first seeks the common recommendations from several international reviews. It then considers the gaps between these recommendations and typical engineering curricula. Primarily, there is a lack of engineering practice in most programs. The paper then considers required graduate outcomes as expressed in accreditation criteria and how these might be reorganised to provide a different emphasis, focusing on design rather than the technical knowledge that supports it. Examples are provided of design-oriented or project-oriented curricula, which are gradually becoming more common in Australia. However, space precludes discussion of these in detail. Nevertheless, the references provide enough information to seek out more information about, and evaluation of, these programs. Finally, the conclusions encourage all engineering educators to rethink their curricula from one based on engineering science to one based on engineering design.

1 INTERNATIONAL REVIEWS OF ENGINEERING EDUCATION

The US National Academy of Engineering's *Engineer of 2020* report [1] presented a vision for future engineering (my emphasis):

1. … profound impact of the engineering profession on **sociocultural systems**, …
2. … engineers competent to address the **world's complex and changing challenges**.
3. We aspire to engineers in 2020 who will … **expand their vision of design**
4. … an engineering profession that will rapidly embrace the potentialities offered by **creativity, invention, and crossdisciplinary fertilization**
5. … engineers who will assume **leadership positions**
6. … an engineering profession that will welcome **underrepresented groups** to its ranks
7. … engineers will continue to be leaders in the movement toward … **sustainable development**
8. … engineers are prepared to adapt to changes in global forces and trends and to **ethically assist the world**

Further, the report adds:

> *With appropriate thought and consideration, and using new strategic planning tools, we should* ***reconstitute engineering curricula*** *and related educational programs to prepare today's engineers for the careers of the future*

Recommendations from the follow-on report, Educating the Engineer of 2020 [2] are surprisingly non-specific:

1. … students should be introduced to the **"essence" of engineering early** in their undergraduate careers.
2. Colleges and universities should **endorse research in engineering education** as a valued and rewarded activity for engineering faculty
3. … institutions must teach students how to be **lifelong learners**.
4. Engineering educators should introduce **interdisciplinary learning** in the undergraduate curriculum
5. … and explore the use of case studies of engineering **successes and failures** as a learning tool.
6. The engineering education establishment should participate in efforts to **improve public understanding of engineering** and the technology literacy of the public and efforts to improve math, science, and engineering education at the K-12 level.

Perhaps it is not surprising that change has been slow given these non-specific recommendations.

The UK Henley Report [3] highlights the need for three kinds of engineers:

1. The engineer as **specialist** recognises the continued need for engineers who are technical experts of world-class standing.
2. The engineer as **integrator** reflects the need for engineers who can operate and manage across boundaries, be they technical or organisational in a complex business environment.
3. The engineer as **change agent** highlights the critical role engineers must play in providing the creativity, innovation and leadership to shape the industry in an uncertain future.

The engineer as change agent is in tune with recent calls for greater innovation in engineering and many other disciplines, innovation being seen as the underpinning of the future world economy, e.g. [10, 11].

Sheppard, Macatangay et al. [4] concluded that:

1. "… the **tradition of putting theory before practice** and the effort to cover technical knowledge comprehensively allow little opportunity for students to have the kind of deep learning experiences that mirror professional practice and problem solving.
2. The **lab** is a missed opportunity: ... **Design projects** offer opportunities to approximate professional practice, … However, these opportunities are **typically provided late in the undergraduate program**.
3. Concerns with **ethics and professionalism**, …, have long had difficulty finding meaningful places within this historical model
4. Further, the dominant curricular model, …, with its attendant **deductive teaching strategies**, … does not reflect what the … research on learning suggests about how students learn and develop
5. The central lesson that emerged from the study is the imperative of **teaching for professional practice**"

The authors articulate **four principles of curriculum design**:

1. *Provide a professional spine*
2. *Teach key concepts for use and connection*
3. *Integrate identity, knowledge, and skills through approximations to practice*
4. *Place engineering in the world: encourage students to draw connections*

Robin King [6] examined engineering and engineering education in the Australian context and made six recommendations:

1. increase the **public understanding** of engineering … particularly in schools;
2. **clarify educational outcomes and standards**;
3. **develop best-practice engineering education**;
4. attract a **higher proportion of women** and other under-represented groups;
5. **increase staffing and material resources**; and
6. **promote stronger collaborative links with industry**.

In *A Whole New Engineer*, Goldberg, Somerville et al. [8] trace the innovation that has emerged from Olin College in Boston and the on-going collaboration with the iFoundry at the University of Illinois. They describe the six minds that engineers need to develop: the **analytical** mind, the **design** mind, the **linguistic** mind, the **people** mind, the **body** mind, and the **mindful** mind. However, when we look at curricula, it is the first that gets by far the most attention.

Interestingly, Trevelyan [9] reinforces the need for the *linguistic* mind – his research (and that of others) shows that engineers spend 60% of their time communicating. The *people* mind has a couple of dimensions; engineering is inherently a team activity and it works in the service of humanity. *People* dominate engineering, although this is sometimes not obvious from the curricula.

Goldsmith, Reidsema et al. [12] in *Designing the Future,* report on an industry-academic workshop at the culmination of a project that investigated design-oriented curricula. The **top six trends** affecting engineering practice were identified as: impacts of globalisation, environmental awareness, breadth of knowledge base, engineering systems, rapid changes in technology, and the research/teaching dilemma. The **top six capabilities** were: personal and professional skills and attitudes, communication, design, teamwork, systems thinking, and design of engineering systems.

Despite all these calls for educational innovation, change in traditional curricula, departments and faculties is hard. Ruth Graham [5] interviewed more than 100 change agents from around the world and identified four key attributes of successful change:

1. Change is often initiated by a **significant threat**, e.g. falling retention, recruitment and employability of graduates. Interestingly, such change is often driven by those with **industry experience** and/or new hires.
2. Change needs to be **systematic and connected**, bringing a new wholeness to the curriculum. In the process, it creates a **new brand**, which is easy to sell to others.
3. Change happens at the **Departmental level**, driven by the Departmental Head. Trust in this person's judgement is key, e.g. in future promotion applications that might flow from leadership of change activities.
4. **Change is difficult to maintain**. Successful programs involve most staff, involve systematic evaluation of the program that encourages sustained innovation and reinvention.

Reidsema, Hadgraft et al. [13] identified a structure for systematic change at national level in Australia, involving a partnership between industry, Engineers Australia, the Australian Council of Engineering Deans and the Australasian Association for Engineering Education. Unfortunately, little progress has been made.

Beanland and Hadgraft [7] reviewed the opportunities for transformation of engineering education from a global perspective. Key conclusions include:

1. engineering education must be exciting, relevant and socially responsible, particularly to attract more women
2. the curriculum should be focused on personal transformation based on student-centred learning
3. graduates must become creative, informed, capable and responsible
4. use the extensive literature to inform the transformation of curricula
5. improving curricula will increase completion rates and provide better graduates
6. engineering employers, governments, accrediting authorities and professional engineering associations, must support the universities to achieve transformation
7. changes required are significant – structure, content, delivery modes, objectives, student experiences, staff responsibilities and roles, assessment, etc
8. changes to how universities operate will be necessary – policies, practices, facilities
9. transformation needs to be part of each Faculty's strategic plan

It is also worth reminding ourselves of the context in which engineers work, which is neatly summarised by the Code of Ethics, in this case from Engineers Australia [14].

Demonstrate Integrity, Practise Competently, Exercise Leadership, Promote Sustainability

If these behaviours are to be developed in graduates, then we need a curriculum that is much more complex than teaching applied science and mathematics.

1.1 Summary

It is clear that we need new engineering curricula, ones built around the 'whole engineer' rather than the idea that if an engineer knows enough applied science, the rest is simply application.

Curricula need to expose students early to the complex and challenging problems emerging in the world. Not only will these problems help them to learn design and problem solving, but they will naturally integrate the full set of professional skills: teamwork, communication, ethics, sustainability, etc. – the people-oriented skills that have been shown to be the heart of good engineering.

This is not to argue that mathematics and science are not essential skills for an engineer. However, they need to be seen as analysis tools that serve design in the same way that prototyping does: engineering analysis is simply numerical prototyping. However, design must usually satisfy a complex set of requirements, not all of which are resolvable into neat scientific equations.

2 TYPICAL CURRICULA

When we examine most curricula, they remain reliant on lecture driven subjects covering traditional topics – statics, dynamics, solid mechanics, thermodynamics, fluid mechanics, materials, circuits, control, etc. Many of these subjects last well into third year, giving students in four year programs little time to develop engineering problem solving skills for a world where sustainability considerations are essential – less material and energy use over the product's lifecycle.

For example, an analysis of the civil engineering program at my own university shows the following breakdown:

Table 1. Breakdown of Civil Engineering program at the University of Technology Sydney

Category	**Units**
General purpose modelling (mathematics and computing)	3
Physical and chemical science	2
Professional skills (communication, design, economics, project management, business)	5
Basics of civil engineering (surveying, construction, materials)	4
Structures	6
Water, hydrology, environment	3
Geotechnics	2
Transport	1
Research and Project	2
Elective	4
Total	**32**

Of these 32 units, there is a design element in 6 units, accounting for perhaps 50% of each unit, which means that around 10% of the entire program is design. This is not unusual in my experience, having been involved in accreditation panels at a number of universities.

2.1 What are the alternatives?

There are now many universities that have moved to problem and project driven curricula, in whole or in part. Aalborg University in Denmark led the way (since 1974), with 50% of each semester devoted to project-organised problem-based based learning (POPBL) [15]. Other variations have been adopted at the University of Queensland in Chemical Engineering [16], Olin College, the University of Illinois's iFoundry [8], the Royal Melbourne Institute of Technology (RMIT) [17], Monash University in Civil Engineering [18], Central Queensland University [19], Victoria University in Melbourne, Deakin University [20], and many others around the world.

These curricula implement the recommendation from [4], namely a project-driven spine, typically in each semester of the program, beginning in the first. This project subject is usually 25% or 50% of each semester's work, sometimes expanding to 100% of the final semester of a program.

Two recent innovations in Australia are worth noting: Charles Sturt University (CSU) [21] and Swinburne University [22] are both using 100% project-based curricula supported by industry mentors and online learning. Students are immersed in engineering from day one, effectively providing an on-campus apprenticeship model. In the case of

CSU, students take 3 semesters on-campus before spending 4 x one year work placements, supported by online learning materials and summer schools for upskilling.

Oddly, unlike the medical discipline, engineering has not widely embraced problem/project-based learning, even though engineering is fundamentally a project-driven profession.

The following section takes a deeper look at how program outcomes are represented in accreditation criteria and in some of the research that has examined what it is that engineers do.

3 ENGINEERING OUTCOMES

First of all, what is the nature of engineering? The Define Your Discipline project [23] in Australia conducted more than 20 meetings with more than 200 engineers and asked them one simple question: what *do* graduate engineers do in your company? Participants were encouraged to write as many tasks as they could think of and then to organise them into meaningful clusters.

These meetings revealed *three* sets of interlocking skills: *process or problem-solving skills* such as investigation, modelling, design, management, impact assessment; *technical skills*, which define each engineering discipline, and *generic skills* such as communication, teamwork and collaboration, ethics, innovation, etc.

The *generic* skills are common across every discipline at the university, the *process* skills define engineering, as opposed to other disciplines, and the *technical* skills define the particular discipline of engineering, e.g. distinguishing a civil engineer from a mechanical engineer.

These three sets of skills should come as no surprise since they are easily found in the accreditation guidelines around the world: The International Engineering Alliance (the Washington Accord), ABET, EURACE, Engineers Australia, etc.

However, the three skill sets are rarely articulated in quite this way. Rather we are given a long list of competencies that begin by emphasising an understanding of mathematics and physics. The research shows that *design, investigation and modelling* are the core of engineering practice. Rewriting the accreditation guidelines to put design first could shift our thinking on engineering curricula. The professional skills have also been given greater importance, since this is where engineers spend most of their time, as shown above.

In Table 2, the Engineers Australia competencies have been reorganised, while preserving the original numbering, which demonstrates which elements have been moved to new places. The design criteria have been placed first, since these are what engineers do, supported by the people-oriented skills and the technical skills. This presentation should spark new ideas for curriculum designers beyond ‘let’s start with more mathematics and physics’.

Table 2. Engineers Australia Stage 1 Competencies (reorganised)

Engineering Design Ability	
2.3.	Application of systematic engineering synthesis and design processes.
2.1.	Application of established engineering methods to complex engineering problem solving.
2.2.	Fluent application of engineering techniques, tools and resources.
2.4.	Application of systematic approaches to the conduct and management of engineering projects.

Professional and Personal Attributes

3.1. **Ethical** conduct and professional accountability.
3.2. Effective oral and written **communication** in professional and lay domains.
3.3. **Creative**, innovative and pro-active demeanour.
3.4. Professional use and management of **information**.
3.5. Orderly **management of self**, and professional conduct.
3.6. Effective **team** membership and team leadership.

Knowledge and Skill Base

1.1. Comprehensive, theory based understanding of the underpinning **natural and physical sciences**
1.2. Conceptual understanding of the **mathematics**, numerical analysis, statistics, and computer and information sciences.
1.3. In-depth understanding of **specialist bodies of knowledge** within the engineering discipline.
1.4. Discernment of knowledge development and **research** directions within the discipline.
1.5. Knowledge of engineering design practice and **contextual factors** impacting the discipline.
1.6. Understanding of the scope, principles, norms, accountabilities and bounds of **sustainable engineering practice** in the specific discipline.

This ordering makes a little more sense, by focusing on design and professional practice. However, the wording does not capture the essence of engineering in my opinion. Describing engineering as the 'application of design processes' makes it sound like a recipe-following exercise, which design rarely is [24].

The Australian *Threshold Learning Outcomes* for Engineering and ICT [25] also begin with 'identify the problem':

Graduates will have the knowledge and skills to:

1. Identify, interpret and analyse *stakeholder needs, …*, using *systems thinking,* while recognising *ethical implications* of professional practice.
2. Apply *problem solving, design and decision-making methodologies* … to meet specified *requirements*, including *innovative approaches* …, while demonstrating *information skills* and *research methods.*
3. Apply *abstraction, mathematics and discipline fundamentals* to analysis, design and operation, …
4. *Communicate and coordinate* proficiently …, working as an *effective member* or *leader* of diverse teams, using basic tools and practices of formal *project management.*
5. Manage own time and processes effectively by *prioritising competing demands* to achieve *personal* and *team goals, with regular review* of personal *performance* …

These five statements capture what it means to do engineering and are complementary to Engineers Australia's Stage 1 Competencies listed above.

4 NEW CURRICULA

So, the first step in transforming curricula is rethinking the centrepiece of engineering from technical skills to identifying stakeholder needs and requirements, using design thinking and decision making. Engineering is not merely 'the application of science'.

The second step is to investigate a range of project-centred curricula from the 100% projects at Swinburne and CSU to 50% (Aalborg University, VU, CQU, Deakin) or even 25% models (UQ, RMIT) as referenced above.

The University of Technology Sydney is currently engaged in remaking engineering curricula in just this way using Studios as the focus of student learning [26]. In fact, a key transformation is not just the curriculum but each student's engagement with it, through a portfolio of career development, beginning in the first semester. Studios focus on student learning through a learning contract. Students become reflective practitioners in their own personal development – EA's point *3.5: Orderly management of self, and professional conduct*.

However, the real challenges are in shifting academics' thinking about how students learn their discipline, a topic for another paper.

5 CONCLUSIONS

The literature demonstrates that there is an urgent need to redesign engineering curricula, with design and problem solving at the heart of the student experience; this should also be reflected in the way that accreditation guidelines are articulated.

There are many examples from around the world to show how this can be done. However, the evidence is that it is difficult and the main impediment is the academic system, which emphasises technically-focused research as the most important academic activity. A lack of industry experience in the academic workforce is also a serious issue [27].

As the 21st century develops, we see a greater emphasis on innovation and the creation of new enterprises. A recent study showed 40% of my university's students expect or desire to start their own businesses.

So, our engineering curricula need to be sufficiently flexible to develop those three types of engineers identified in the UK Henley Report: the technical specialist, the integrator and the change agent.

We academics need to take up this challenge, to demonstrate our own capacity for change and innovation.

ABSTRACT

One of the difficulties in ICT education in regular lessons is that educators must teach all the techniques for developing systems within a limited time frame, despite the fact that students cannot learn without actually experiencing the various techniques. This paper introduces an educational method of software development that is collaboration between the industry and the community. The method is based on the principles of Project-Based Learning (PBL). The proposed method features learning software development technology by incorporating an actual citizen support system using the Spiral model [1]. The project was supported as one of the Ministry of Internal Affairs and Communications IoT Service Creation Support Project. The purpose of the IoT Service Creation Support Project is to identify specific problems that should be overcome when creating and deploying IoT services through demonstration projects, build a reference model that will help solve the issues, and promote data utilization etc. In addition, it is to play a leading the role lead to the development and maintenance of the necessary rules for the IoT service. Students developed a citizen support system. Through this activity students learned about the idea of entrepreneurship. By use of the developing system and prototype system for citizens, as well as from the results of responses to a questionnaire survey, we found that the method developed is effective for improving citizen life.

INTRODUCTION

ICT education is difficult to deliver in a regular classroom setting because of the need to introduce all the techniques for developing systems in a limited amount of time. In addition, it is impossible to teach students practical requirements analysis, architectural design, etc., in such a limited time frame. The primary reason this is not possible is the inability to teach such techniques without actually having experienced them.

This paper introduces an educational method of software development that collaborates with industry and community. The method is based on Project-Based Learning (PBL) and applied to the students of the Department of Information and Computer Science in Kanazawa Institute of Technology (KIT). The method features a learning software development technology by creating an actual citizen support system using the Spiral model [1]. The software development method, using the Spiral model, is compatible with the Project Design Program in KIT [2].

The project was supported as one of the Ministry of Internal Affairs and Communications IoT Service Creation Support Project. The purpose of the IoT Service Creation Support Project is to identify specific problems that should be overcome when creating and deploying IoT services through demonstration projects, build a reference model that will help solve the issues, and promote data utilization etc. In addition, it is to play a leading the role lead to the development and maintenance of the necessary rules for the IoT service. The group of Nonoichi City, NEC Solutions Innovator Co., Ltd., Yoshida Advertising Co., Ltd., Kanazawa Institute of Technology and Kanazawa Technical College was selected for this project.

This paper explains in detail the practical project that was carried out in Nonoichi-City. The city, located in Ishikawa Prefecture in Japan, requested the development of the ICT system for citizen support. We carried out an educational project in which the students themselves thought about a given problem and methods of problem-solving by collaborating with companies and the city. In an effort to solve the given problem, we developed an information terminal bus stop and submitted proposals to Nonoichi-City. The developed system comprised five sub-systems: Timetable and Transfer Guidance System, Children's and Elderly's Observation System, Disaster Countermeasure System, Advertisement System, and City Public Relations System. This system features image recognition software and provides service matching for each individual.

From active engagement with the project, students learned how to listen to individual requests, analyze the requests, and create the system. In addition, they also learned how to conduct the operational test, solve extraction problems, and improve the system. The project allowed students to receive hands-on education, and at the same time, also had favorable effects on the community. In fact, when using the prototype system for the citizens and conducting a questionnaire survey, we received numerous comments on its effectiveness in improving citizen life.

This paper is organized in the following manner. First, we explain the KIT Education system. Second, we present the intended characteristics of an ICT education in collaboration with Nonoichi City. The educational method of software development using PBL and the Spiral model is addressed in detail. Third, we explain their effects. Lastly, we offer a summary of the material presented.

1 SIGNIFICANCE OF PROJECT ACTIVITIES IN KIT

In KIT, students are educated in two wheels of curricular education and extracurricular education (Fig. 1). The Project Design Program (PD) is the backbone of the curricular education, it is carried out as a regular class for all students and has made great progress [2-3]. Project-Based Learning (PBL) is applied in PD courses.

Extracurricular activities also play an important role in KIT. They include YUMEKOBO Projects (YUMEKOBO is a Japanese term which refers to the Factory for Dreams and Ideas), Department/Lab-related Programs, Collaboration Programs with Industry and Community[4], and Internship Programs. In these activities, students can set up objectives by themselves and learn from the successes and failures. For example, YUMEKOBO Projects are self-directed projects to develop students' technical competence [5]. There were 16 YUMEKOBO Projects in 2016 [6]. The education project described in this paper worked as an extracurricular activity.

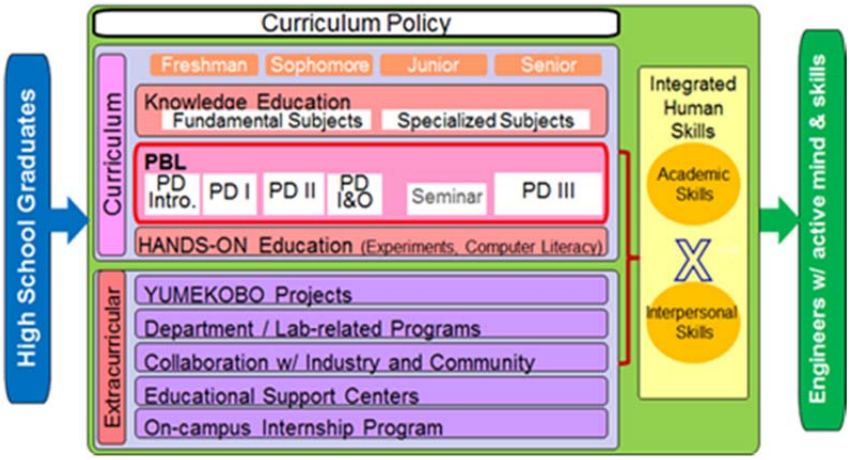

Fig. 1. KIT Pedagogical System

Fig. 2 shows the problem solving flow used in PD education at KIT. In PD education, students learn the flow of the discovery of the problem, clarification of the problems, creation of ideas, selection of ideas, and implementation of the idea. In addition, even in extracurricular activities students will use the same flow to solve problems. The difference between the regular curriculum classes and the extracurricular projects is that the flow is carried out repeatedly in the extracurricular projects.

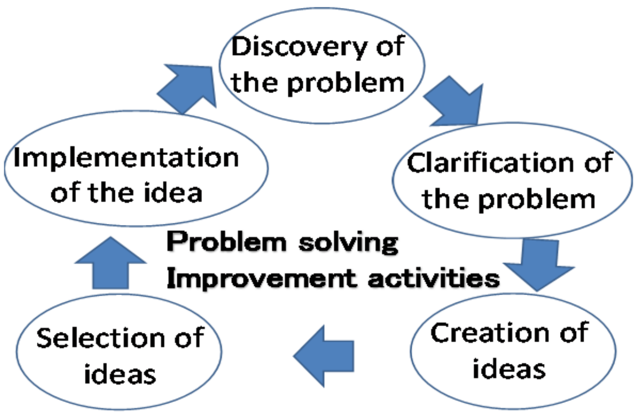

Fig. 2. Problem solving, improvement activities flow

In extracurricular activities, by repeating the improvement flow, students examine deep and complex matters. Students form a team with different grade levels unlike classes and execute the project. One benefit of working as a team consisting of different grade levels is that senior students are able to develop leadership skills. In addition, conducting the project allowed juniors to learn the importance of the regular curriculum classes.

2 DETAILS OF THE CITIZEN SUPPORT PROJECT ACTIVITIES

2.1 Project Objectives

Society is constantly changing. We believe that we need the ability to respond flexibly to this change. We also believe that the ability to create new value challenging and leading society in a better direction is important. We actively work on society's problems, improve society and think that the university's mission is to produce human resources that support the country. We are engaged in entrepreneurship education using the development of regional innovation system.

We believe that the three requirements for becoming a global leader are as follows, and we aim that students master these abilities. In the field of information processing, especially the change is intense, we felt that training of following skills is necessary, and decided to teach them through by the project activities.

A) Awareness / understanding of shifting trends and needs in society

B) Connect one’s interests an/or abilities

C) The mentality and action to make full use of one’s resources and solve social challenges

We decided to work on improvement of citizen's life, targeting a city with a university. We thought that it was meaningful for students who are citizens to solve the problems owned by them and to enrich the lives of citizens. We decided to develop a citizen support system to solve the city's problems and enrich the lives of citizens.

The other purpose of the citizen support project is to nurture software development abilities and to develop problem solving skills of students by developing an ICT system for citizen support. We aim to improve the student's skill as an information processing engineer by educating system design method while actually creating the system, which is difficult to teach in the outcome. In addition, the system we developed was designed based on the five-year plan issued by the Nonoichi-City so as to contribute to the revitalization of the city and the improvement of citizen's living. With the cooperation of Nonoichi-City, this project carried out many activities. In addition, we also received the cooperation with local companies in developing the system.

We aim to establish a system that transcends the mere extracurricular activities of students, and can actually be used in society, and that can operate in the long term and moisturize society. It aims not only to construct a system but also to manufacture a bus stop of an information terminal and to construct a mechanism which can actually be used as a citizen support system. This includes monetary aspects including maintenance. It is a great significance for students to consider and construct a system that can actually be commercialized. In addition, if the system has social significance, we think that its significance will be greater.

First of all, the project had done the discovery of the problem, clarification of the problem. In the discovery of the problem and clarification of the problem, we conducted based on Nonoichi City's five-year plan published by Nonoichi City. We addressed the following five problems to be resolved within a 5-year plan of Nonoichi-City. The correspondence division of Nonoichi-City is also shown below.

I. Timetable and Transfer Guidance ⇨ Area Promotion Section

II. Watch over of Children ⇨ Child-Rearing Support Section

III. Watch over of the Elderly ⇨ Regional Comprehensive Support Center

IV. Disaster Countermeasures ⇨ Environmental Safety Division

V. Advertisement and City Publicity ⇨ Secretary Public Relations Section

One of the more obvious characteristics of Nonoichi-City is that all of the 112 bus stops are consistently designed in the small city as 3 km in length and 3 km in width. The character named "Notty" is popular in Nonoichi-City, and this character is also used for the bus. Therefore, we tried to solve the problems that Nonoichi-City had, by making the information terminal bus stop which was shaped like a "Notty".

2.2 Flow of System Development

For the development of the system, students from the first year to the fourth grade of the university organized a team. It is a project of about twenty students. Within the project, system design and development were shared and carried out with a flexible group structure. In addition to the students, the project was conducted with four professors and two administrative staff members.

Fig. 3. Matching event of the Ministry of Internal Affairs and Communications Hokuriku

Since finding the problem and clarification of the problem was completed, students created the idea. As the ideas were completed, students submitted the ideas to the G space matching event hosted by Hokuriku of the Ministry of Internal Affairs and Communications, and we were awarded the Grand Prix. After that, Students developed a system specification from an idea, and led to their creation of a prototype system. The Ministry of Internal Affairs and Communications Hokuriku hosted a matching event with companies that supported the commercialization of the information terminal bus stop. We participated in a matching event and introduced the prototype system. Fig. 3 shows the situation of the matching event. Students were explaining about the system to companies. Thanks to this event, we found a company willing to cooperate in its commercialization. Subsequently, we developed prototype improvement activities in collaboration with companies as well as Nonoichi-City.

The system we created to solve the problem consists of the following five subsystems.

I. Timetable and Transfer Guidance System
II. Children's and Elderly‘s Observation System
III. Disaster Countermeasure System
IV. Advertisement System
V. City public relations System

The Information terminal bus stop has built-in Android terminal using the 3G network.

2.3 Interaction between Spiral Model and Problem Solving Procedure of KIT

The Waterfall model refers to a development model that gradually advances each development phase from system requirement definition to design, manufacturing and testing[7]. The Spiral Model is a technique to gradually expand the function by creating the main program and incorporating user's request[1]. Agile is one of the development methods to minimize risk by adopting a short development period unit called "iteration", meaning "quick", "agile"[8]. Each has its own strengths and weaknesses, and many Japanese companies are developing by Waterfalls model.

In the developing of the citizen support project, we selected the Spiral model. The merit of the Spiral model is that it is easy to reflect feedback and respond flexibly even when there is a problem regarding specification change from to feedback after trial use. As a result of repairing and repairing problems repeatedly, it is possible to finally create a quality system. We had to fix the system again and again, and it takes time to develop, but we thought that it would be good for students to wear skills slowly. Also, development could be done at the development pace that suit their abilities.

In utilizing the Spiral model, students were able to learn software development methods. In addition, the problem-solving flow adopted by KIT has much in common with the Spiral model, working together effectively and complementing each other. For example, if problems were found in the prototype, they were identified and solutions were devised. Based those discussions, solutions were developed and systemized. Since the Spiral Model is specifically designed to develop a system incrementally, it is easy to actualize the ideas through the programing.

3 RESULTS AND DISCUSSION

To better determine the impact and potential success of the system we created, we conducted a questionnaire survey among 50 citizens concerning the prototype of the information terminal bus stop within the bus-stop waiting area. Fig. 4 illustrates students conducting of the questionnaire survey.

One question concerned the “necessity of the information terminal bus stop.” As a result, thirty respondents answered that such an informational terminal was “necessary.” When asked why this was needed, 19 people answered that it was effective for improving the convenience of public transportation. In addition, 10 people responded that it would contribute to the safety of the local society. Another 9 individuals responded that they expected regional vitalization to occur as a result of providing information about the city to citizens. The responses to this survey are evidence that our system is expected to improve convenience of public transportation as well as provide effective regional vitalization and improve city safety.

Fig. 4 Demonstration of information terminal bus stop and questionnaire survey

Through the development of the information terminal bus stop, students conducted the request analysis, learned the techniques needed to build the system, and the request from the city and its citizens were satisfied. In addition, they learned the method of operation testing, extraction of the problem, and problem-solving skills.

Such hands-on, real-life interactions are important because students do not have the chance to experience in the regular curriculum classes. The knowledge that students gained as a result of this research has the potential to help society as a whole because of the skills they develop while participating in it. Students taught with respect to one another in the same school year and learned together. Throughout this educational project, students developed abilities required within society. For example, seniors gained leadership skills while they, and other project members, improved communication skills and acquired an understanding of cooperative learning as well as a sense of responsibility.

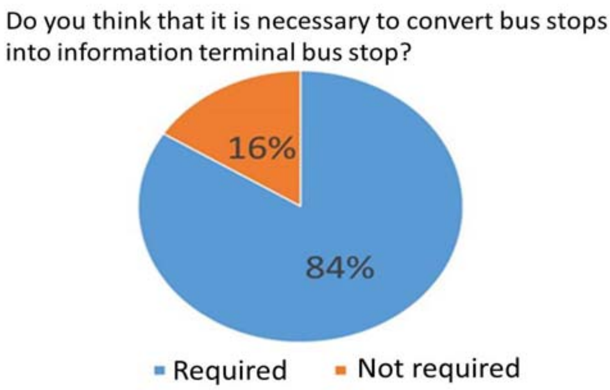

Fig. 5. Questionnaire Result 1

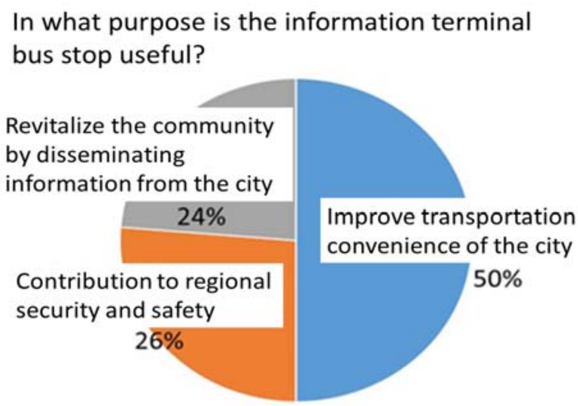

Fig. 6. Questionnaire Result 2

4 SUMMARY AND ACKNOWLEDGMENTS

This paper introduced the educational method of software development that encompasses the collaboration of industry and community. The method is based on Project-Based-Learning (PBL) and features learning software development technology by developing an authentic citizen support system using the Spiral model [1]. The project was supported as one of the Ministry of Internal Affairs and Communications IoT Service Creation Support Project. The purpose of the IoT Service Creation Support Project is to identify specific problems that should be overcome when creating and deploying IoT services through demonstration projects, build a reference model that will help solve the issues, and promote data utilization etc. In addition, it is to play a leading the role lead to the development and maintenance of the necessary rules for the IoT service. As a result of using the prototype system for the citizens and conducting a questionnaire survey, it is clear that our system can work to improve citizen life.

When implementing this bus stop project, we were supported by the industry-university cooperation office in KIT. We are very grateful to the member of the industry-university cooperation office. In addition, we are very grateful to those in Nonoichi-City that worked with us.

ACKNOWLEDGMENT

Part of this research was funded by the Ministry of Internal Affairs and Communications IoT Service Creation Support Project.

ABSTRACT

The present study aims to integrate creative strategies of "brainstorming" and the "six thinking hats" in an "industry 4.0" project-based course, in an attempt to cultivate creative climate and creativity for mechanical engineering and digital learning students. Participants were forty-three students enrolling in a project-based course. A post-survey of creative climate was conducted and students' final projects were evaluated for creativity. Results of regression indicate that, among the eight dimensions of creative climate, "sufficient resources" and "managerial encouragement" can significantly explain 19.4% of the variance in students' creativity ($F(8,32) = 2.200$, $p = .054$). The effects of "sufficient resources" on students' creativity was very likely resulted from the creative strategies employed in the course, while the effects of "managerial encouragement" may come from creative strategies as well as the teacher's supportive behaviors. Suggestions for future studies are provided.

Conference Key Areas: Curriculum Development, Engineering Education Research, Student Cooperation

Keywords: Creative-Thinking Strategy, Creative Climate, Creativity

INTRODUCTION

In the era of the "4th industrial revolution (industry 4.0)" where the combination of the Internet and future-oriented technologies results in innovation in industrial production [1], the development of creativity, whether in family, school, organization, etc. has gradually drawn attention worldwide. Creativity is indeed one of the key 21st century skills indicated in Trilling and Fadel's study [2]. Nevertheless, college students in the Taiwanese vocational education system have long been oriented towards pursuing higher education, and there is a lack of creativity competence; students generally do not know how to design and actualize creative products independently. Creative-thinking strategies are crucial for enhancing students' creativity. Studies have shown that teachers could utilize creative-thinking strategies for bringing out students' potential to create [3]. At the same time, the construct of a "creative climate" is a focal point among scholars when discussing factors for inducing creativity [4]. In view of this, the design of the present study is to integrate creative strategies into an "industry 4.0" project-based course, in an attempt to promote creative climate and to further spur students' creativity.

1 LITERATURE REVIEW

1.1 Creativity

Woodman et al. [5] suggest viewing creativity in social systems from the following components: (i) creative persons, (ii) creative processes, (iii) creative situations, (iv) creative products, and (v) the interactions of these components. Creativity can be viewed as a person's innate ability to create, a thinking process that generates novel solutions to problems and original, useful products. The environment one situates in can stimulate or suppress one's creativity, and vice versa. Creativity can also result from the complex interaction of personal traits, thinking process, and environment, and it manifests in various forms such as products or concepts. Mayer [6] found that most scholars have indicated that creativity relates to new and useful products, including concepts and concrete objects, and that "product" is the desirable target of assessment if one wishes to test the substantive ability to create. Consequently, the present study evaluates students' creativity based on the products created in a project-based course.

1.2 Creative climate

When it comes to cultivating students' creativity in classroom, the learning environment is one of the most essential factors [7]. The climate of an environment, such as an organization, is conceptualized as the shared beliefs or perceptions about the contingencies, requirements, and practices of the organization [8], such as employees' perceptions on the leaders' management styles, degree of workload, relationships among colleagues, and autonomy in conducting one's work. Environmental factors spurring creativity can be further characterized as creative climate [9].

Amabile, Conti, Coon, Lazenby, and Herron [10] developed "KEYS" to assess the climate for creativity. It is implied from "KEYS" that creativity could be enhanced through socialization of the work environment. "KEYS" comprises eight dimensions: (i) *organizational encouragement* refers to an organizational culture that judges employees' ideas fairly, constructively, and supportively. It rewards and recognizes creative work and utilizes mechanisms for generating new ideas. (ii) *supervisory encouragement* refers to supervisors who set clear goals, are able to establish good working environment, serve as a work model, and show confidence in employees. (iii) *work group supports* refer to being in a group where members communicate well, open to various ideas, trust, and feel committed to their work. (iv) *freedom* indicates the autonomy and control over what work to do and how to proceed. (v) *sufficient resources* are access to sufficient resources, such as funds, materials, facilities, and information. (vi) *challenging work* indicates that people realize they should endeavor to deal with challenging works and important projects. (vii) *realistic workload pressure* are lack of excessive time pressures, unrealistic expectations for employee's productivity, or distractions from work. (viii) *lack of organizational impediments* refer to an organizational culture that lacks internal political problems, conservatism, destructive internal competition, and harsh managerial structure.

1.3 Creative-thinking strategies

The purpose of creative-thinking strategies is to increase students' creativity via customized activities [11]. In the present study, the strategies are "brainstorming" and the "six thinking hats". "Brainstorming" [12] is a method for yielding a large number of ideas that are to be processed later. The guidelines of brainstorming are: (i) Negative judgment of ideas should be deferred until later. (ii) Truly wild ideas are desired. (iii) The more ideas produced, the greater chance of yielding useful ones. (iv) Elaborating on others' ideas to produce new ones [13]. Studies have found that brainstorming can help learners organize and arrange their thoughts [14]. The other strategy, the "six thinking hats", [15] allows one to pinpoint a certain type of thinking at a time, and competence in thinking can increase by adopting appropriate thinking styles. The six thinking modes are white (objective facts), red (emotion), black (critical), yellow (optimistic), green (creative), and blue (organization). It has been supported by studies that the six thinking hats can help one conceive more original and a larger number of ideas [16].

2 RESEARCH PURPOSE AND QUESTIONS

The purpose of the present study is to integrate creative strategies into an "industry 4.0" project-based course at a college to cultivate creative climate, and to examine if students' creativity could be promoted through such strategies. Especially, the main research question is how do creative-thinking strategies influence students' creativity?

3 METHOD

3.1 Instructional contexts: Creative-thinking strategies and project-based course

Authors of the present study and the instructors who teach project courses collaborated to develop a target course for the present study that is based on a pre-existent project-based course that teaches theories and practice of "industry 4.0". The main focus of the target course is to integrate creative-thinking strategies with industry 4.0 instructions. The course contains four topics: industry 4.0 and sensors, innovation and application in web of things, cyber physical system, and application of big data and cloud in industry 4.0. The course lasted one semester (eighteen weeks), with each session lasting four hours (one-hour practice class included), six of which comprising two hours of creative thinking instructions across the whole curriculum. Students were required to yield a plan for their projects related to "industry 4.0", such as creating a smart vending machine or an autonomous vehicle. Students then had to further bring their plans into practice. They were instructed to work in groups, utilizing creative-thinking strategies by discussing topics related to "industry 4.0" and cooperatively developing final projects. For instance, brainstorming was used to conceive how to apply web of things onto the final project. The "six thinking hats" was used to help students contemplate the contents and feasibility of the final project, as well as help them examine how big data can be applied into industry 4.0.

3.2 Participants

The participants were forty-three students who majored in mechanic engineering or digital learning at a college in Taipei city, Taiwan. They were students who took a project-based course called "Industry 4.0: Theory and Practice" in 2016.

3.3 Procedure

Assessment was conducted using James' revised version of "KEYS" [17] to measure creative climate, where students indicated their perceptions on each dimension of the course climate. The procedure included two stages: (i) *An "industry 4.0" project-based course* was carried out. (ii) *The creative climate questionnaire* was conducted at the end of the course with students' final products being evaluated by experts. Interviews were also carried out, where students were instructed to answer interview questions based on their experience in, perceptions on, and suggestions toward the course.

4 RESULTS

Excluding two invalid cases, there are in total forty-one effective cases for analysis. For the overall regression model, the eight dimensions of creative climate significantly explain 19.4% of the variance in creativity score ($F(8,32) = 2.200$, $p = .054$). We then aimed at finding which dimensions can significantly explain the creativity score, and results indicate that two dimensions have such effects. The one with a stronger effect is "sufficient resources" ($\beta = .469$, $p = .049$), and the other is "managerial encouragement" ($\beta = .396$, $p = .046$). The positive coefficients of both variables indicate that with an increase in "sufficient resources" or "managerial encouragement", students' creativity also increases.

Table 1. Multiple regression analysis for explaining creativity score on dimensions of creative climate

	Unstandardized Coefficient		Standardized Coefficient		
	B	*Se*	Beta	*t*	*p*
(constant)	55.318	10.665		5.187	.000
Freedom	1.686	3.528	.088	.478	.636
Challenging Work	-.282	2.665	-.022	-.106	.916
Managerial Encouragement	4.816	2.320	.396	2.075	.046
Work Group Supports	6.395	4.454	.512	1.436	.161
Organizational Encouragement	-5.637	4.341	-.443	-1.299	.203

Lack of Organizational Impediments	-4.291	3.848	-.278	-1.115	.273
Sufficient Resources	5.777	2.822	.469	2.047	.049
Realistic Workload Pressure	-2.199	1.842	-.230	-1.194	.241

5 DISCUSSION

The present study integrated creative-thinking strategies with a project-based course, finding that “sufficient resources” and “managerial encouragement” can predict students’ creativity performance. It is suggested that he application of creative strategies in the course may have successfully provided students with sufficient resources for tackling problems. For instance, in the interviews, many students gave credit to the “six thinking hats”; one student expressed that “the ‘six thinking hats’ allowed me to organize my ideas with structure” and that the method helped “create phrases in each category so there was something to discuss”. When students could not find essential resources at hand, they were nevertheless able to find creative ways to find replacement by using the “six thinking hats” method. Moreover, students were asked to make a list of the resources they needed for their projects during the “brainstorming” sessions, which very likely helped them know better about their resources. In addition, the requested resources, may it be tools, money, or other supplies, were provided immediately to students most of the times.

The increase of students’ creativity may also come from teacher’s encouragement. The design of the course may have encouraged the teacher to explain clearly the project goals to students, support students’ ideas, show confidence in them, and evaluate their works fairly and supportively. Furthermore, it is indicated that students did not show fear when proposing ideas, because the principles of “brainstorming” and “deferment of criticism” were emphasized by the teacher. All of the aforementioned elements of “managerial encouragement” resemble those of transformational leadership, which can increase employee creativity. This outcome is supported by the results of previous studies, such as that providing followers with confidence in them to excel at work [18], or that providing individualized consideration such as recognition and encouragement can both enhance creativity [19].

6 CONCLUSIONS

In the present study, “brainstorming” and the “six thinking hats” are applied in an “Industry 4.0” project-based course to enhance students’ creativity through creative climate. It is indicated that “sufficient resources” and “managerial encouragement” have positive effects on students’ performance on creativity. It is likely that creative strategies provided participants with thinking structures, when listing and organizing their resources, for example. Meanwhile, the teacher established a good learning environment by setting clear goals, recognizing students’ contributions, and encouraging ideas without harsh criticism. Thus, a conclusion can be drawn, that is, both mechanisms, “sufficient resources” and “managerial encouragement”, can help develop students’ creativity. Nevertheless, while the present study implies that creative strategies such as “brainstorming” and the “six thinking hats” do have positive effects, their effects manifested only in two creative climate dimensions. Thus, it is suggested that future studies employ other creative strategies to test whether they can trigger other aspects of the creative climate that can affect students’ creativity.

ABSTRACT

This study investigated the effect of interdisciplinary collaborative learning on creativity and communication. Students received lectures regarding Internet of things, big data, cloud computing, mechatronics, sensors, embedded systems, and cyber physical systems, as well as training in creative thinking strategies such as brainstorming and six thinking hats. Two classes of students participated in the study. In the experimental class (n=43), undergraduate engineering students (n=22) were partnered with graduate students from digital learning (n=21), whereas the comparison class (n=41) consisted of only undergraduate engineering students

without interdisciplinary collaboration. In both classes, activities were conducted in groups. Each group created an interdisciplinary project. The data included their responses of using the creative thinking strategies and project proposal. The results found that the experimental class scored significantly higher in both the six thinking hats and brainstorming strategies than the comparison class. Moreover, the groups in the experimental class presented higher quality of proposal and provided considerably more descriptions of their projects. Through the interdisciplinary collaboration, engineering students were able to analyse a problem and examine a piece of work from multiple perspectives, create more ideas, and enhance written communication skills.

Conference Key Areas: engineering education research, curriculum development

Keywords: creativity, interdisciplinary collaboration, smart manufacturing

INTRODUCTION

This study investigated the effect of interdisciplinary collaborative learning on creativity and communication. Previous studies have revealed that engineering students are not comfortable thinking creatively, considering their designs for real-world contexts [1], and communicating effectively [2]. Council on Competitiveness (2005) has identified creativity or innovation as a major keystone of a knowledge economy [3]. We must equip engineering students not only with analytical and technical skills, but also with creative thinking [1]. The effort was mainly through art or design studio. Moreover, one of the factors that significantly affect engineering graduates' success in the workplace is oral and written communication [4]. Ford and Riley (2003) summarized four common approaches to enhance engineering students' communication skills: (1) integrating communication instruction within engineering curricula and including writing assignments within engineering courses, (2) collaborative instruction between engineering departments and communication departments, (3) promoting technical communication minor, and (4) establishing supporting systems such as communication and writing centers [2].

Previous effort on enhancing engineering students' creativity and communication was mainly through art or collaboration with the communication programs [1,2]. Inspired by McNair, Newswander, Boden and Borrego's (2011) interdisciplinary and multidisciplinary teaming approach [5], the current study created a course co-instructed by faculty from the education and engineering departments. The course focused on topics of Industry 4.0 and creative thinking. The graduate students from education and undergraduate students from engineering formed interdisciplinary teams that mimic the cross-functional and cross-disciplinary team structure of industry. They had to collaborate closely in all creativity activities and to write a proposal as they would work in the industry. Their performance in creativity and writing through this interdisciplinary collaboration was evaluated.

1 METHOD

1.1 Participants

Two classes of students participated in the study. In the experimental class (n=43), undergraduate engineering students (n=22) were partnered with graduate students from digital learning (n=21), whereas the comparison class (n=41) consisted of only undergraduate engineering students without interdisciplinary collaboration. The engineering students were junior or senior students, mostly from mechanical engineering and a few from electronical engineering. In both classes, activities were conducted in groups. The group sizes were controlled between 3 to 4 students. Each group created an interdisciplinary project, wrote up a proposal, and carried out the project.

1.2 Instruction

According to Borrego and Newswander (2008), for a cross-disciplinary engineering education collaboration to be successful, the participating parties should mutually understand and appreciate the nature of knowledge in each other's academic disciplines [6]. To build up this understanding, two faculty members from the education department and two from the engineering department as well as two students from each department have met every week since the semester before the course. All course content and activities were created, tested, and modified together.

The course met three hours a week for 10 weeks. Students received lectures regarding Internet of things, big data, cloud computing, mechatronics, sensors, embedded systems, and cyber physical systems, as well as training in creative thinking strategies such as brainstorming and six thinking hats. The discussing topics in the creativity activities were all based on the lecture topics and contributed to their team projects. At the end of a lecture, each group practiced the creative thinking strategies and attempted to integrate the lecture content into their project through brainstorming or six thinking hats. The group projects were chosen from the following topics: smart production in car industry (AGV, smart machine arm, and object identification system), intelligent vending machine, Gamebike (combining gaming and biking), and intelligent storage/ retrieval systems. The students had to turn in a proposal at the 10th week. They then spent another 8 weeks to carry out the proposal.

The education students played multiple roles as users, project managers and trainers for human resource. They were expected to learn engineers' perspectives from the engineering students and gain experience in leading a project and human resource training and development. The engineering students played a role as engineer. They learned to communicate with engineers from other fields such as electronic engineering, mechanical engineering and education. They would learn users' and managers' perspectives from the education students.

1.3 Data collection and analysis

The performance of the two classes in creativity and proposals was compared. Their responses of using brainstorming strategy were graded based on quantity/ the number of ideas (0-5), appropriateness to the topic (0, 1), practicality (0, 1), and uniqueness (0-3). The scores ranged between 0 and 10. For the six thinking hats strategy, the criteria were quantity/ the number of ideas (0-6), appropriateness to the perspectives of the hats (0-6), and uniqueness (0-3). The scores ranged between 0 and 15. Finally, the proposal was graded by two instructors with inter-rater reliability .83, and their length/word counts were calculated. The scores were compared using the t-tests.

2 RESULT

2.1 Creativity

The data of the experimental class showed that the digital learning students performed significantly better than the engineering students in the use of the six thinking hats strategy, but not in the use of brainstorming (Table 1). The education students were more able to evaluate a case or problem from different perspectives. However, they created about the same amount of ideas as the engineering students. Among the engineering students, the experimental class scored significantly higher in both the six thinking hats and brainstorming strategies than the comparison class (Table 2). In other words, even though both groups received the same creativity training, the experimental group, working with the digital learning students, were able to perform significantly better.

Table 1. Performance of creativity thinking between the engineering and digital learning students

	Engineering (n=21)	Education (n=20)	t(39)	p
Brainstorming	7.78(1.40)	8.24 (1.01)	1.21	.23
6 thinking hats	10.96 (1.27)	14.22 (7.28)	2.02	.05

Table 2. Performance of creativity thinking between the engineering students in two groups

	Experimental group (n=21)	Comparison group (n=48)	t(67)	p
Brainstorming	7.78 (1.40)	6.83(1.50)	2.45	.017
6 thinking hats	10.96 (1.26)	6.63(2.06)	10.09	<.001

2.2 Proposal writing

In comparing the proposal done by both groups, the teams in the experimental group presented higher quality of proposal and provided considerably more descriptions of their projects than those in the comparison group, $t(12.68)=4.13$, $p=.001$.

3 SUMMARY AND ACKNOWLEDGMENTS

Through the interdisciplinary collaboration, engineering students were able to analyze a problem and examine a piece of work from multiple perspectives, create more ideas, and enhance written communication skills. The results revealed that student interdisciplinary teaming is a successful approach to prepare engineers for the global and knowledge economy. The student collaboration creates invaluable learning experience. Future curricula may consider to offer such authentic learning experiences.

ABSTRACT

The challenges of the 21st century call for supporting Continuing Engineering Education, a topic that is of increasing importance to universities worldwide. Furthermore, attracting new talents (women among others) into Engineering Education, is a key-element in contemporary higher education. Although the offer of studying programs alongside work has grown in recent years, there is still a need for research in context of accompanied studies and a lack of theory-based development in didactic concepts for learning professionals. This paper contributes to this research discourse and aims to generate new insights in a threefold way: (1) by specifying challenges and innovative approaches for accompanied studying programs in Business Engineering; (2) by explaining the theoretical framework for the methodical arrangement of exemplary engineering courses for non-traditional students; and (3) by describing first experiences with the concept during the development and implementation in selected engineering course. This paper also provides a new perspective on how to meet gender aspects. In this context, the influences of interdisciplinary orientation and student- centered course design were analyzed by using semi-structured interviews with female students.

Keywords: Continuing Engineering Education and Lifelong Learning, University-Business cooperation, Curriculum Development, Attractiveness of Engineering Education, Gender and Diversity

INTRODUCTION

Recent socio- political and economic developments call for supporting Continuing Engineering Education, [1, 2]. Furthermore, attracting new talents into Engineering Education is a key-element in contemporary higher education. One approach to react to the strong demand is the broadening of the target group with an increased focus on non-traditional students, as in [3]. Although the offer of studying programs alongside work has grown in recent years, there is still a lack of theory-based development in targeted didactic concepts and associated empirical findings [4]. There is still a need for research in context of accompanied studies and student-centered contact with the specific target groups of learning professionals, e.g. [5, 6]. This paper contributes to this research discourse. In section 1, the term “non-traditional student” is specified and a professional master’s degree program for this specific target group is presented. Section 2 deals particularly with the theory-based course design for this specific type of students and illustrates the Model of Educational Reconstruction as an applicable framework for this methodical educational arrangement. Building on this, section 3 illustrates the implementation of the concept in selected engineering courses and describes first experiences with the concept. Section 4 covers gender aspects and debates, which framework conditions of the concept are beneficial to the motivation and participation of female students. Additionally, it addresses the opportunities that arise for occupational study programs. This approach generates empirically grounded knowledge on the theory-based course design for learning professionals and contributes to the translation of engineering education research to practice. Universities will have to face these challenges, in living up to the requirements of change processes in a sustainable manner.

1 CHALLENGES FOR CONTINUING ENGINEERING EDUCATION

1.1 Occupational study programs in Germany

Due to the demographic transformation into ageing societies and to the rapid pace of technological change, the European University Association recommended in their 2008 preamble [1] to open to continuous education. Since then, German universities have followed this central educational objective by opening universities to lifelong learning more intensively and by supporting flexible learning pathways, as in [2]. The group of lifelong learners is very heterogeneously, a differentiation is made in [7]. This paper focuses on the employed learners, those working full or part time during their studies. They show “…circumstantial diversity with age differences, disabilities, employment status, caring responsibilities or different financial backgrounds” [8]. Additionally, we find a diversity regarding their motivation, interest, and learning styles, e.g. in [7, 8]. In Germany, there are more than 130 engineering occupational master programs. Of these offered study programs, 13 are master programs in business engineering, which build the focus of this paper.

1.2 Professional master’s degree program in Business engineering: Research-to-practice contribution with focus on non-traditional students

To attract new target groups (women among others) as well as prospective students from working life, an innovative Professional Master´s degree in Business Engineering was conceived, that focuses on the intersection of management and technology. As a specific feature, the engineering master´s program is designed for *non-traditional students*, experienced professionals who do not originate from a technical field and who are repeatedly confronted with technical issues in the occupational context. The business engineering master’s degree is scheduled on the weekend. It is a four term (90 credit points) extra-occupational study program combining engineering content with business specialization[1]. This Master of Science program is now in its fourth iteration. The courses are designed with a focus on industrial production, combining the complex links between technology, business, and management. In the first semester scientific and engineering fundamentals are taught. The second and third semester include more detailed engineering courses as well as more complex topics

[1] To which extent these specific features of the study model are appealing especially to women, see within the scope of the qualitative study in Sec. 4.

that deal with the connection between technical and economic content. Throughout the entire study period, complementary courses offered that accompany the study (for example courses in leadership). The master course "Applied Engineering Sciences" presented exemplarily in this paper to explain the theory-based course design is from the field of scientific and engineering fundamentals.

2 THEORETICAL FRAMEWORK AND RESEARCH-BASED COURSE DESIGN OF THE EXEMPLARY ENGINEERING COURSE

2.1 The Framework of Educational Reconstruction with focus on continuing engineering education

The focus on non-traditional students´ pathways brings up the challenge of linking the course design and the individual learning process of the employed learners. This contribution dedicates to the research desiderates, e.g. [4-6], by presenting the Model of Educational Reconstruction. This theoretical framework was choosen because of its consistent student-centered conception. In general, the Model of Educational Reconstruction is a research framework widely used in scientific education, see [9, 10]. There are first results concerning the implementation of this adopted model in engineering, [11]. As a novelty, the model is implemented with a focus on employed learners, who do not originate from a technical field. Fig. 1 shows the generic model adapted for the field of engineering sciences and non-traditional employed learners.

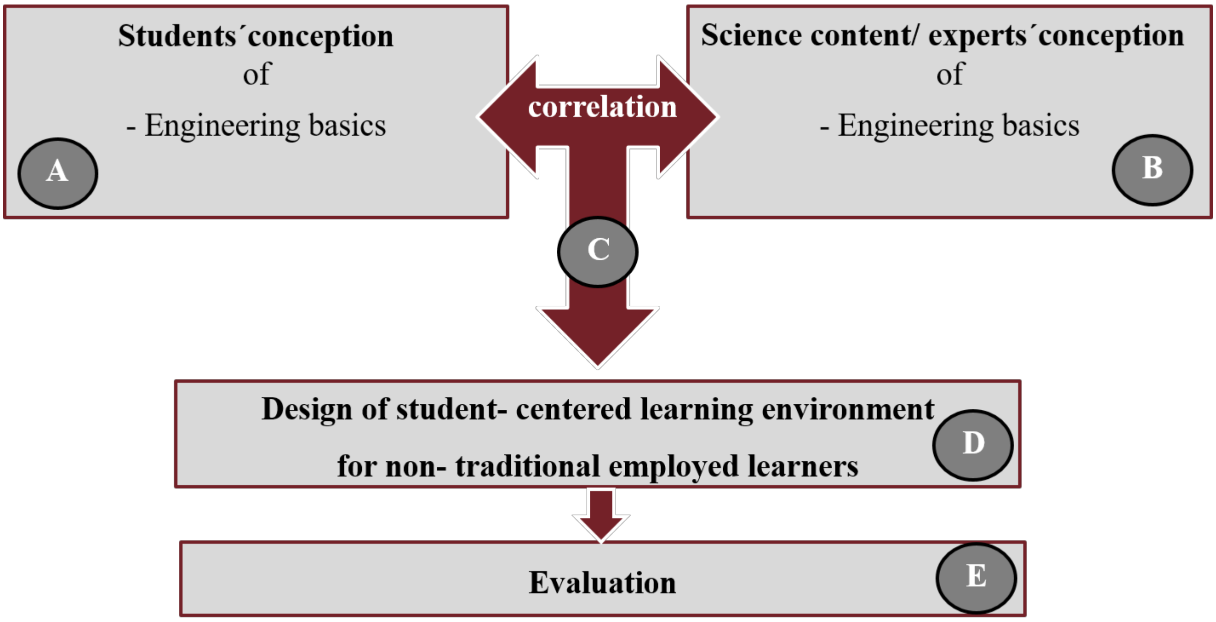

Fig. 1. The Model of Educational Reconstruction with focus on non-traditional employed learners: framework and methods used, based on [9, 11]

Constructivist learning theories, such as [12], build the theory framework, described by the teaching methodology triple [13]. There are three elements that interact- detecting of students' perspectives, the clarification of experts' conceptions, and the didactical structuring, [ibid]. The unique characteristic of this triplet is the equivalence of experts' conceptions and students' perspectives. To implement the model, all research steps A to E (see fig.1) had to be completed. In order to grasp the variety of aspects in a scientific manner, quantitative and qualitative research methods are used, according to the research steps A to E in fig. 1. Firstly, the students' conceptions about electro-technical concepts must be collected based on students' self-report (**step A**). Besides socio-demographic data, motivation to study, and background on technical subjects, the report contains questions for the employed learners about the current conception of engineering basics. At the same time, the scientific clarification as analysis from the literature is being prepared in **step B**. What do the concepts look like in science? What scientific models exist and where can coherences and limits of the imagination be found? In **step C**, the learners' understanding about the technical theory is reflected and differences between scientific perspectives and the perspectives of the learners are disclosed. Are there existing correspondences to the scientific model? At which point can you build on the learners' conceptions? As result of this correlation, research-based findings exist that prescribe what should to be regarded while introducing terms, concepts, and models to the students. Furthermore, with the goal of fostering the students' learning process, the result of the correlation proposes the appropriate interventions that are most likely to be successful. These interventions will be developed in correspondence to the framework of constructivist learning theories and implemented in an engineering teaching practice in **step D**, the result of this design phase is presented within the next section. A final evaluation by students' self-reports on knowledge base within the engineering topics (**step E**) delivers empirical evidence about the effectiveness of the courses. Further feedback from the students has been incorporated into the process of improvement of the course design.

2.2 Research-based Course design

The course design is based on the theoretical frameworks of constructivist learning theories, e.g. [12], and gender theories focusing on STEM education, e.g. [14,15]. Besides these theoretical frameworks, the analysis of the Educational Reconstruction has shown that the methodological-didactic construction of the courses needs to be understood consequentially from the learning process of the individual. The analysis of the students' conception revealed an extremely wide spread in every evaluated category (e.g. age, professional position, motivation). On the one hand, the self-rated technical backgrounds are similarly low. On the other hand, the non-traditional learners have expanded professional and everyday experience. This extended experience is not yet actively retrieved by the student as transfer knowledge, the link to the field of engineering cannot be made yet. Referring to the Model of Educational Reconstruction, these students' conceptions must be incorporated actively in the student-centered course design, to achieve an individual and optimal adoption for the best possible learning outcome and the development of the students' professional competence. The engineering fundamentals should be presented with a focus on taking up the professional context. The mentioned directives are anchored in the didactic concept, presented below:

- *Lectures* as on-site-events with practical examples selected from priority themes (presented by the teacher or the students),
- *Laboratory sequences* integrated into the lectures to anchor the link between theory and practice and to get hands-on experience, and
- *Guided self-study* with reflection and feedback phases (step-by-step conception of exercises fitted for the non-traditional target group, self-control must be possible permanently, online part with the teacher for feedback and reflection).

The theory-based course design guarantees appropriate learning activities for the non-traditional students and supports their learning process.

3 IMPLEMENTATION AND FIRST EXPERIENCES WITH THE CONCEPT

As an example, the implementation of the didactic design into the master course "Applied Engineering Sciences" is presented, currently running in its fourth iteration. The course provides the engineering basis for further specialist modules. Required outcomes are developing technical-methodological skills (e.g. basic techniques and engineering practices in the handling of simple electrical and mechanical problems) and developing practical knowledge (e.g. the analysis of equivalent circuits, the use of appropriate methods and instruments). The ***laboratory sequences,*** developed and adapted to the core statements of the course, are integrated to overcome the analysed specific deficits in practical preliminary knowledge. Driven by the theoretical framework, the laboratory session is often the starting point of the lessons. This procedure enables to address the unique deficiencies and baseline knowledge of the non-traditional students. Within laboratory group work, a continuous self-control of the students is applied and technical and methodical questions arise. Due to the small number of students, an individual support of the learning process during the experiments is possible, so the students can work out their necessary technical and methodical competencies. The ***guided self-study time*** was intended to adapt to the strong heterogeneity, to overcome deficits, and to strengthen the individual learning process of the employed students. Exercises concretely oriented toward the contents of the given lectures have been conceived that can be permanently worked on and that provide the opportunity for self-control. Detailed solutions are available for the student to validate their own considerations or to initialize the solving process. Content of the lectures is continually worked on, and a connection to the lectures is made by "do it yourself". In this way, the self-study time supports flexible learning styles and forms individual ways of learning.

First ***positive experiences*** with the concept are available. In the survey, every student self-reported a knowledge increase in electrical engineering. A further reference is the fact that every previous student completed the module and the exam successfully. In respect to the didactic course design, the employed students mentioned the practical laboratory part as very helpful. As additional effects, the integration of practical experiments shows an increase in interaction between teacher and students, a transfer of this culture of closer communication and direct feedback into the lectures became possible. Through the interweaving of economic problems and engineering education, a win-win situation for students and teachers is given. Not only is the transfer of new technologies into professional practice supported, but the students' input from their professional experience provides valuable feedback for the full-time courses.

4 QUALITATIVE STUDY TO EXPLORE GENDER ASPECTS

4.1 Targets and theoretical foundation of the study

Female employees are, as initially illustrated, clearly underrepresented in the STEM[2] sector and therefore are, alongside non-traditional students, a further and important target group. The aim of this qualitative study via guideline-based interviews is to analyze, if the professional master's degree program in Business Engineering can be a successful measure to acquire female potential for STEM-studies. Moreover, the framework conditions to successfully address women concerning a further education in engineering will be developed. An important role for the decision to study in the STEM sector play the self-efficacy beliefs, e.g. in [16]. The theoretical construct of self-efficacy was introduced by Bandura [17]. It describes a subjective confidence in one's own competencies to carry out actions successfully and to be able to meet

[2] STEM stands for science, technology, engineering and math.

expectations, e.g. in [18]. These statements are especially relevant in respect to the gender aspect, hence the construct of self-efficacy influenced the theoretical foundation of the guideline-based interviews and their evaluation. In addition, references to practical orientation and interdisciplinarity were examined in the interviews. Among others, Thaler and Hofstätter [19] highlight in this context a strong link concerning the decision for an engineering study.

4.2 Methodology and implementation of the analysis

Regarding the continuing engineering education, goals of the qualitative study were on the one hand to collect statements regarding the organization of the study model and to the learners' requirements. On the other hand, the interview study is used to identify the students' backgrounds, and the motivation for the field of engineering. For this purpose, the guideline covers the key issues mentioned above. Beside the socio-demographic data, educational background and the motivation to start studying were collected. The recorded interviews have been completely transcribed, while a memo was created for each interviewee. The assessment of the interviews in transcript was done in accordance with the procedure of qualitative content analysis [20] and under consideration of the in 4.1 explained theory. The interview survey includes seven interviews with first and second year female students of the master degree „Business Engineering". Hereafter, the female students will be denoted as interview person (IP 1-7). The women are between 22 and 30 years old, after a bachelor's degree in economics the female students have been working in the industrial sector.

4.3 Selected empirical findings and elaboration of the potentials for Continuing Engineering Education

The analysis of the interviews yielded results on several levels. In this paper, the focus lies on the aspects motivation to study, self-efficacy and student- centered course design. Almost all interviewees stated that the ***motivation to study a technological discipline*** is an insufficient technical know-how and a restricted judgement concerning technical issues and problems. Since they, as a consequence, felt constrained in their professional career an urge to study further in the technical area developed.

> *"And when discussions regarding specific topics arose, I reached my limit when I realized that my dialogue partner could tell me anything. I was not able to validate anything and only understood some problems after asking again or doing further research. That was when I realized that technology interests me and that I want to dive deeper into this topic."* (IP 4)

Concerning ***self-efficacy*** and confidence the analysis of the interviews distinctly indicates that a successful first degree and professional experience in the industrial context are to be interpreted as beneficial. IP 5 describes how she gained insight on the structures of an industrial concern through her occupation and detected that she possesses the skill to position herself technologically:

> *"(…) that is why I gathered all of my courage and said to myself: I have already achieved a lot and have proved myself in my first academic degree, which gave me strength once before. And now I will simply take my chances." (IP5)*

IP 2 shares this experience. She also gained access to technological coherences as well as dismantled barriers through her professional career:

> *"During my occupational experience, I realized that innovation is very fun-looking into the future and trying to see where the (technological) journey will go. But as innovation is always tangent to technology (…) I realized during my professional career that I am interested in these things as well." (IP 2)*

The selected statements confirm the results of the analysis, which prove an increased self-efficacy concerning the beginning of a technical study through previous occupational and academic achievements. Furthermore, the results show the particular importance of a ***strong connection between theory and practice within the master's degree program as well as the significance of interdisciplinary content and a close connection to the professional profile***. Most of the interviewees stated, that they only after the career entry got a clear understanding of professions and possibilities in the technological segment. As for example IP2, *"It was only during my professional career and with growing experience that I came to realize what engineers do".* It shows, that often a vague (or unattractive) occupational profile of the engineer exists, which discourages from a technical first degree. Within this context, Ihsen [21] constitutes that universities offer too few initiatives to renew outdated views on technical course of studies. Additional, the interviewees positively rated the interdisciplinary approach in conjunction with technical and economic study content. They especially underline the possibility to enhance an economic first degree with a follow-up degree in the technical area.

5 CONCLUSIONS AND RECOMMENDATIONS FOR FURTHER WORK

Continuing Education and Lifelong Learning is an exciting and growing research area within higher engineering education. This paper presents a professional master program "Business Engineering", which innovatively targets students without a previous engineering degree. This specific non-traditional target group as well as female students were directly addressed while developing the program. The paper shows that the Model of Educational Reconstruction is well suited to execute a fitting course design for learning professionals in a theory-based manner. This student-centered framework is particularly valuable for the research discourse in this field. With the implementation of the theory-based course design a contribution to the translation of engineering education research into practice was made. The qualitative study with a focus on gender aspects underlines the positive impacts of a strong conjunction between theory and professional experience and of the interdisciplinary adaption of the master program. The next step is to expand the qualitative study on the full-time Master´s to deepen the gender-relevant insights and to explore potentials for the improvement of the master programs. Moreover, the results of the study provide valuable insights for specific student recruitment and counseling.

6 ACKNOWLEDGMENTS

The author expresses her gratitude to the professional students involved for their cooperation and feedback. The author would like to thank the master students of the course "Engineering Education Research", who have actively supported the qualitative research. Thanks to the unknown reviewers for their very useful comments in the early phase of this paper.

ABSTRACT

The aim of this article is to identify and analyse the potential influence of national cultures on the implementation of Continuing Engineering Education training courses, within the context of industrial technology transfer from the perspective of the transferors. Using the example of a Franco-Brazilian programme, which we were commissioned to analyse, our main focus will be to explore how the cultural dimension of time can have an impact on a training course with complex technological contents and high added value. Drawing on Trompenaars' notion of "cultural dilemmas" and that of Demorgon's "adaptive antagonisms", our methodology is based on the analysis of in-depth interviews with French experts

training Brazilian engineers. The purpose of the present study is to identify the most pertinent profile for international trainers with intercultural competences which combine technological expertise, a broad vision of the industrial and cultural context and strategic planning and vision.

Key words: Engineering education, intercultural training, technology transfer, cultural dilemmas, Brazil, France

INTRODUCTION

Setting up high added value Continuing Engineering Education programmes to accompany technology transfer (TT) of systems, equipment and services, in an international, geostrategic and competitive context is both a sensitive and complex undertaking. In addition, cultural differences, such as variations in the relationship with time, space or people may present additional challenges. The in-house trainers in our study, which was commissioned by the technology provider, are confronted with the complexity inherent in this type of training programme. This can lead to strategic, commercial and technological contradictions. They are also exposed to often unknown cultural dimensions which can both represent additional problems and become indistinguishable from the technical difficulties of the programme. If we consider the anthropological dimension of culture as the "*solution to dilemmas"* [1], lack of knowledge of the clients' culture can create contexts which can potentially generate further dilemmas in addition to the original technical and human problems [2] [3].

1 TECHNOLOGY TRANSFER AND TRAINING

1.1 The impact of different concepts of time

The aim of this article is to identify and analyse the difficulties linked to differing concepts of time, one of the key elements which emerged during a study of a Franco-Brazilian TT training programme from the perspective of the transferors. These difficulties were often perceived by the engineer trainers with trainees from different cultures as paradoxical or as insoluble dilemmas. At the same time, we aim to distinguish between the different cultural and technical dimensions of the training programme, drawing on Trompenaars' notion of "*cultural dilemmas*" [1] and that of Demorgon's "*adaptive antagonisms*" [4] [5]. The use of these two notions can facilitate differentiation between the dilemmas inherent in TT and those linked with cultural differences, while also going beyond the descriptive elements of the "*cultural dimensions*" prominent in the Intercultural Management literature which can lead to overgeneralization.

1.2 The dilemmas of technology transfer training programmes

The objectives, contents and implementation of the TT training programme for Brazilian clients in this study, which is the first of its kind, require the engineer/trainer to adapt to three different elements: the requirements of the French company/employer, satisfaction from the Brazilian clients and the complexity and sensitivity of the technology involved in the transfer. Indeed, the trainer must sell his or her company's technology, train the clients and explain how the equipment and systems work but without giving away confidential information or intellectual property. Before embarking on any TT training programme, trainers need to reflect on three imperatives which we identified during the study as: the " *must, will, can dilemma*" [2]. They wonder how far they "*must*" go in transmitting their company's technological know-how without betraying their trust, how far they are "*willing*" to prepare their client to benefit from the technology autonomously and how far they "*can*" engage in their part time role as trainer, for their main remit remains technology design rather than transmission. Contradictions to do with their role and identities as engineering technologist, business engineer and trainer are thus added to imperatives at three levels (employer, client, technology). Finally, the international context requires systematic use of a foreign language, usually English and exposure to foreign cultures. This is the context, characterized by complexity and tensions, for the training programme for exporting industrial equipment to Brazil, which concerns hundreds of trainee-clients with diverse profiles, jobs, levels and backgrounds, to be trained over several years on sites in France and abroad. In France, the training sessions are in classrooms or directly on-site. The training budget, including logistics and other expenses represents hundreds of thousands of euros. The trainers selected by the company have only had a few months' preparation between the signature of the contract and the beginning of the training sessions, a time lapse which is considered too short, as we will see later. At the launch of the preparation for the training programme, the very first trainers displayed several different views concerning the duty, the willingness and the capacity of future potential trainers to design, organize and implement this training programme. This can be illustrated by two extreme reactions, firstly from an experienced trainer who had no doubts about the success of the whole of the programme: *"It's just common sense; each time there's a new trainee you always have to adapt your message to the population".* However, the trainer in the second example takes into account that, for many, the programme represents their first experience of a TT contract towards a foreign client, and seems to doubt the capacity of the company to run a training session: *This tightrope between what we can or cannot say."*

2 ANALYSIS OF A FRANCO-BRAZILIAN TT TRAINING PROGRAMME

2.1 Demorgon's six perspectives approach

In spite of all the contradictions and imperatives of the programme, the premise of this article is that they will not necessarily lead all the trainers to such insoluble dilemmas. In order to analyse the varying degrees of adaptation we draw on Demorgon's multisperspectivist approach where dilemmas are posited as "adaptive antagonisms" [4] [5]. Demorgon stresses the fact that situations can be presented as bipolar opposites but along a continuum, where we have to choose to decide and to act according to two or many demands [5]. This notion of adaptation which is culturally informed, chosen, deliberate and singular in each situation completes the notion of "*cultural dimensions"* in the Intercultural Management literature which is often applied as generalisations which can be measured and expressed as figures [6]. Demorgon considers that these cultural dimensions, such as monochrony/-polychrony, individualism/collectivism are pre-adaptive antagonisms to any decision or action, allowing, for example a trainer in a multi or monocultural context to act either by "*an immediate action*" or by a "*culturally informed action*" [5]. This "*culturally* *informed action*" in every singular situation through "*synchronic adaptation*" operates according to 6 perspectives [3]. These six perspectives include the *field* (religious, political, economic or technological) and the *levels* (individual, corporate and/or national) where cultural interactions take place. Demorgon makes a distinction between what is dependent on *self-organisation or disorganisation* (or dealing with uncertainty) and what is dependent on the *strategy* of the different actors. For example, a company needs a *strategy* which may or may not be culturally influenced, but its members must also be open and adaptable to unpredictable factors or changes which can, in this case, represent cultural or technological dilemmas. For Demorgon, culture is seen as an on-going process which can be changed over time, so s*ynchronic* intercultural situations should also be analysed from the *diachronic* or time perspective.

2.2 Description of a typical training sequence

The Intercultural Management literature identifies numerous cultural differences [7] which can be reduced to three major categories: relationships with people, space and time. For the purpose of this article we have chosen to focus on time, an aspect which was omnipresent in the interviews conducted with the trainers. Each training session is team-taught by two colleagues or by a hierarchical superior and subordinate. There are intergenerational, interdisciplinary and regional differences among the trainees, who are Brazilian engineers. The teaching team is made up of 26 men and 1 woman and represents three hierarchical levels. The classrooms are organized in rows, as in a formal lecture, and allow little contact with the trainees. Each training sequence, in lecture form, lasts 55 minutes, is pre-timed and limited to a maximum of 70 slides. It is prepared in a sequential and monochronic way with provision for a more polychronic phase of exchange and question and answers at the end. However, the trainees, who have received the slideshow one or two weeks before the training session, can look at the slides on their laptops in the chronological order chosen by the trainer or in any order of their choice, at their own pace. The models, tools etc. have been validated through a contractual process and cannot be modified in class. It is forbidden to use or create any other teaching aid. The presentation is filmed and can be interrupted or even cancelled at any time if the client's quality manager or a hierarchical superior from the supplying company deems it necessary. The contact specifies that English should be the working language which also has repercussions on the timing of the session, for, apart from some experienced experts, the trainers interviewed stressed the fact that the use of English added extra presentation time, ranging from 20 to 30%. In spite of this precaution and knowledge of the technical vocabulary made possible by a company lexicon with several thousand entries, they also considered there was a risk inherent in the use of the English language in this context.

3 THE INTERVIEWS CONDUCTED WITH TRAINERS

For the interviews with the trainers, given the complexity of technical training for TT, we looked for a training situation which was the most representative, standardised and recurrent as possible within the same training programme. We opted for training sequences implemented during a morning three- hour session with exclusively technological contents, using a lecture format according to the conditions negotiated and contracted between the supplier and the Brazilian client. By signing a confidentiality contract, we were allowed to observe several sequences of this programme, which allowed us to triangulate the contents of our interviews. These semi-directive interviews with trainers involved in training Brazilian engineers were conducted by three researchers. A total of 102 interviews and coaching sessions were carried out with trainers who were selected from a list of informal networks of both peers and hierarchical superiors. These lists were cross-referenced with the official lists provided by the company's Human Resource Department. The interviews were conducted between 2011 and 2012 on site, near to the informants' workplace. The informants were voluntary and provided with a guarantee of anonymity. Each interviewer followed a guide of seven questions per training sequence. The interviews lasted between 45 and 90 minutes and were recorded, transcribed and analysed.

4 DIFFERENT CONCEPTS OF TIME EXPERIENCED DURING THE TRAINING SESSIONS

In the following section we present three types of classes which reveal cultural dimensions connected with time. We differentiate, in order of complexity between introductory sessions, common core sessions and integrated systems sessions. The introductory sessions of the programme concern general principles and are taught by general engineers with contents which do not have high stakes and represent low industrial, technological or industrial risks. However, the informants were surprised by unexpected interruptions by the trainee/clients during the formal lectures, which is a good illustration of the cultural dimension of polychrony [8]. This situation becomes more complex when the training session deals with the technological problems specific to a common core session. Here it is no longer a question of transmitting more or less abstract knowledge but to transmit contents in the form of problem-solving activities which require a high level of participation from the trainees and reveals new relationships with time.

> *"For example, typically for the Brazilians you have to be careful (…) they don't use the past. The past for them is now. Everything which is going to happen afterwards is the future. You don't only provide results, you deal with work in progress. It's not because you've done something before. Everyone has their history, everyone has their experience but they are there from now and for tomorrow (…). When you presented your class it's good to say 'I've got 22 years' experience and 19, 000 hours of design'. But that, for them, was before. Now it's how is that going to benefit them. 'I'm going to be able to support you because your needs are to be able to create a system with automated elements which are a little more modern than what you have at the moment and in that phase I'm going to transmit my knowledge which you will be able to transmit to the next people etc. etc.' When the objective is presented like that (…) you can get the Brazilians on board."* (Part-time trainer and expert)

In designing the materials, the trainers take great care to involve the trainees by using a problem-solving approach, "*by dealing with demanding work in progress*". The ultimate aim is to achieve complete autonomy for the trainees so that they can train their future colleagues in their company in Brazil. This approach reveals cultural dimensions with different orientations to past, present and future [9] [1] which have a direct impact on the delivery of the training programme. In this example, the trainer tries to gain legitimacy through an experience which can only remain abstract and in which the trainee only sees an individual, professional status and, what is more, from the past. This only has a value if the trainees perceive that it can provide support for their future problem-solving in the immediate present of the sequence. The trainers as providers *must not, will not* and sometimes *cannot* (for strategic reasons or because they *cannot* have a complete overview of the industrial system as a whole) link together the past, present and future of the technological knowledge and know-how of their company without risking giving unauthorised information about experiences or innovations which must remain company property, regardless of the message transmitted to the trainees. Information about the future can only concern content specified in the client's contract and its sensitive character must sometimes remain vague for the trainers themselves, who do not have a global view of the whole system and equipment. On the other hand, the client-trainees try constantly to link past, present and future, in order to obtain information about recent concrete experiences, ongoing productions, or research and development projects so they can plan their own projects and future designs. This tendency for Brazilian culture to closely link past, present and future is confirmed in the literature [9]. This quote also reveals evidence of "*Long term orientation"*, or LTO, [6], another time orientation, closely associated with the previous one. This time orientation is not only also a characteristic of Brazilian culture, according to the literature, but reinforces the strategic element of the project which is planned to be implemented over several years. The link to the future, in an immediate present, forces the trainers to become very explicit and immediate concerning their objectives, contents and teaching design.

The second example is of an integrated systems session*,* which, although it was also designed as a lecture with a sequential and monochronic development, requires polychronic reactions from the trainer. The informants referred to the recurrent difficulty of the trainers who, in the here and now of the session have to have general knowledge of the global equipment system at the same time as highly specialised technological knowledge. In parallel, the trainers must also be extremely reactive to all the questions asked, although the profile of specialist giving priority to a monochronic development of the class in order to explain the technology in detail presents the risk of the expert transmitting too much information or confidential information and no longer being able to respect the timing of the training session.

> *"We have technological barriers which we have fixed ourselves which mean that we cannot reply to all of the questions. So, there, the trainer deliberately gives a vague answer. The question is asked again. And then finally the trainer is pushed to his limits. And the trainer, he falls down. He falls down literally on the spot, he collapses physically. We've already seen that. The trainer (….) bombarded with questions from the client, fell down. Because there's stress, the wish to do things right and eventually he is pushed to his limits and then he cracks up. So, that's why, during training sessions we systematically have the trainer and the Module coordinator. So that the Module coordinator can support the trainer and if it goes too far he can interrupt the class."* (Part-time trainer and expert)

The vast majority of the trainers interviewed highlighted the stress felt during the strictly timed training sessions when they found themselves with the "*must, can, will,* *dilemma*" [6] having to reply but not being able or willing to reply to a multitude of questions both general and specific, sensible or incomprehensible, without being able to distinguish between those that came from genuine learning needs or from manipulation.

5 SIX PERSPECTIVES TO ANALYSE THE TRAINERS' DILEMMAS

Demorgon's six perspectives theory, at the individual, *"synchronic level*" of the trainer, allows us to distinguish between antagonisms or dilemmas of cultural origin from other "antagonisms", while revealing the connections between them. For instance, with the cultural dimension of time, in a situation with a monochronic tendency, the trainer will adapt more easily to the "*must, can, will, dilemma*" [2], whereas polychrony, especially if it is experienced as pressure, loss of control and anxiety can transform it into an insoluble dilemma. Demorgon's theory highlights the fact that a synchronic cultural "*antagonism*" such as polychrony – monochrony can be reinforced by "*strategy*". In a power struggle between client and supplier the client is less inclined to adapt and can use, consciously or unconsciously, the cultural dimensions which suit him or her for strategic purposes. As we have seen, a group of Brazilian trainee-clients can strategically use polychrony which they culturally manage better than the French trainer, who is also almost isolated, to obtain more information, particularly if the trainer is already limited by contract to a monochronic, pre-arranged training sequence. The strategies used by the trainees are themselves generated and reinforced by the "*globalised, technological, competitive*" activity sector [5] of TT. It is therefore fundamental to know as much as possible about the history of the client's culture in its *"diachronic perspective"*. In this way, the French trainer can or cannot manage the complexity that Demorgon calls "*self(dis)organisation*" which characterises any international context at an "*individual, corporate and national level*". This is consistent with research by Lin & Berg [10], who concluded that, while prior international experience on the part of the transferor could enhance TT performance, it could also increase their bargaining power by limiting the flow of technical information.

CONCLUSION

In this article we have highlighted some of the influences of cultural dimensions on training Brazilian engineers by French trainers in the context of TT. We have explored and analysed how the national culture of the trainees can have an impact on the implementation of a training sequence with complex technological content and high added value. Demorgon's six perspectives theory, particularly the notion of "*adaptive antagonisms*" allows us to isolate, observe and analyse the cultural dimensions influencing the interaction. These "adaptive antagonisms" can be of different kinds and represent contradictions or mixed messages in a national, monocultural situation but additional cultural dimensions in an international context. We have concentrated more specifically on the "adaptive antagonisms" linked to time but as we have seen, synchronic adaptation also integrates interpersonal and spatial relationships. The interviews with trainers and our classroom observations revealed the emergence of two opposite and complementary trainer profiles, either implementing a training sequence through "*immediate action*" or "*culturally informed action*". The coexistence of these two "*antagonisms*" in the training team led the company to set up trainer partners in order to reduce the risk of failure for the client, the company and the trainers themselves. It appeared that the profile of senior expert with a global view and specialised knowledge was more able to deal with certain "*adaptive antagonisms*". At the company level, these senior expert trainers, demonstrating a capacity for long-term planning, also tried to participate in the company strategy from the outset of the negotiations for TT. In the contract, they tried to reduce in advance the influence of a training session organised in an exclusively monochronic manner, for they already realized during the negotiations that their Brazilian partners were extremely polychronic. The part-time expert trainers with a stabilised professional ethos seemed more confident in public and more easily able to appropriate the cultural ethos of different countries [3] in complex and difficult geostrategic situations. This led them, in the company under study, to set up very informal networks to exchange good practice. Based on this reflexive practice, it would seem pertinent for them to co-design training programmes for trainers in international contexts including intercultural pedagogy for industry.

ABSTRACT

This paper elaborates on a form of university–industry cooperation called 'collaborative PhDs'. Engineers working at companies or governmental organisations get the opportunity to do a PhD at the university. The aim of these science-based collaborations between academia and industry is to increase the impact of research on sustainable development. However, to fulfil this promise, how should doctoral engineering education for collaborative PhD tracks look like? A literature search, a benchmark on successful doctoral education programmes, in-depth interviews with 10 PhD candidates and their supervisors, as well as observations of meetings, revealed the requirements for a track that is consistent with the relationship and everyone's interest in it, as well as the needs and talents of the PhD candidate. The conclusion of the research is that collaborative PhD candidates come to the university to conduct research, but do not intuitively fit into the academic world. Some feel squeezed between their jobs as, for instance, project managers on the one hand and doctoral candidates at the university on the other hand. This research led to 10 recommendations for setting up a track within the graduate school.

Conference Key Areas: Continuing Engineering Education and Lifelong Learning / University-Business cooperation

INTRODUCTION

Many institutes for higher education maintain good contacts with business and governmental organisations. It is from these contacts that professors regularly recruit talented candidates for PhD projects. These PhD candidates remain stationed elsewhere and their companies granted them part-time leave to follow a PhD programme. The added value of this PhD research can be significant. Knowledge and insights developed by PhD candidates can be applied in practice immediately – which is in line with the 'Europe 2020' goals and the need to speed up the process of sustainable development.

The Deltas Infrastructures & Mobility Initiative (DIMI) and Delft Energy Initiative (DEI) at Delft University of Technology (TU Delft) have launched a pilot for this group of PhD candidates who are employed not by the university, but by companies or governmental organisations interested in the same research themes. They are called ‘contract PhDs’ and their trajectories ‘collaborative PhD tracks’. These PhD candidates defend their dissertations at TU Delft. Their theses must meet the same requirements as the fulltime employed PhD candidates at TU Delft.

The goal of these collaborative PhD tracks is to jointly develop knowledge that is useful for transforming practice and at a sufficient level for a PhD defence. These PhD tracks strengthen the cooperation between the university and industry and this interaction increases the potential for innovation. Especially for research with a link with practice, these PhDs have an advantage over regular PhDs in understanding the context and having access to practical data. However, what sounds appealing in theory is not so easy in practice. Not only is the time available for research a problem for externally based candidates, but they spend a relatively large amount of time learning to do research (searching for literature, formulating research questions, selecting research methods, etc.). It is sometimes years since they last attended university, which means that they possess a great deal of practical experience but need to be trained as scientific researchers. Furthermore, former research shows that implementing innovations generated by PhD projects is not a matter of course. Moreover, the competences needed for a future career in industry and the competences needed in a PhD project do not always correspond [1]. An important condition to fulfil the promise of sustainable development is that these collaborative PhD trajectories run smoothly. The research question therefore is: *What does doctoral engineering education for collaborative PhDs look like?*

We will discuss doctoral education from the broader perspective of the knowledge triangle, the interplay between research, education and innovation (chapter 1). In chapter 2, the interests of all parties involved will be discussed. In the third chapter a need analysis will be described. A series of interviews were held with supervisors, PhD candidates and companies in order to identify the specific needs of each party and be able to co-design a tailor-made track within the graduate school. In chapter 4, the outline of the track will be revealed. Finally, the conclusion describes in 10 recommendations how these pathways can be made more efficient and more effective.

1 COLLABORATIVE PHD TRACKS IN THE PERSPECTIVE OF THE KNOWLEDGE TRIANGLE

Joint PhD projects are a promising form of research collaboration, connecting universities to firms or governmental organisations. One organisation alone cannot achieve the goal of developing critical knowledge for sustainability challenges. For example, to accomplish integrated design and management for resilient, durable infrastructures or system integration in the energy sector, universities, companies and other institutions need to collaborate for a longer period of time. Technological change and economic success no longer depend solely on capital and labour; they require knowledge and other intangible entities like the interaction between public and private organisations and their ability to refresh: 'renewal capital' is an equally important driver of national growth [2]. A PhD project in this context therefore entails not only the training of an individual to become a scientific researcher, but also a collaborative project in which new knowledge is developed that should lead to innovation. These collaborative PhD projects are a way to implement the knowledge triangle.

The Lisbon Agenda introduced the knowledge triangle at the dawn of this century in order to enhance Europe's competitiveness. As shown in figure 1, the knowledge triangle links together research, education and innovation, with special platforms and processes on its three sides. It replaces the traditional one-way flow of information, from research to education and from educators to students, with a circular flow between the three corners of the triangle.

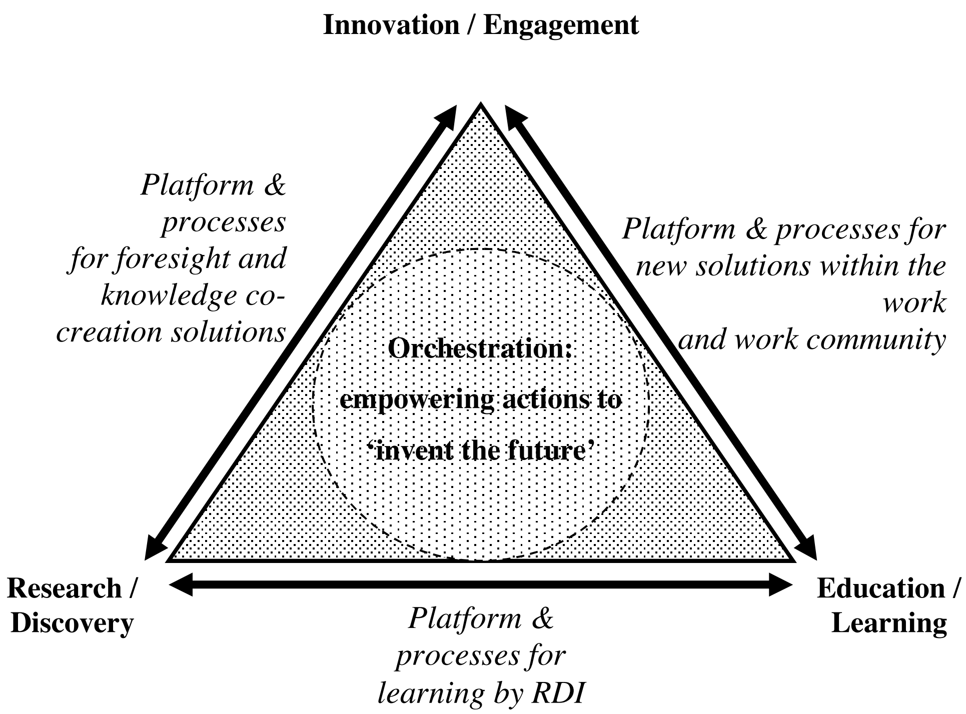

Fig. 1. The Knowledge Triangle [3]

The concept of collaborative PhDs covers all corners of the knowledge triangle. First of all, these PhD candidates are lifelong learners, educated to be scientific researchers. Doctoral education is therefore a form of continuing engineering education. Moreover, these PhD candidates can be involved in ordinary education. Second, the learning process of PhD candidates is strongly linked to research. The aim of the PhD study is to contribute to science, therefore delivering new knowledge. At the same time, these PhD candidates are incorporating the third corner of the triangle in ensuring sustainable economic or societal innovation. So this PhD concept offers tremendous opportunities for education, research and innovation, provided that these processes are well designed.

2 NEED ANALYSIS: THE INTERESTS OF ALL PARTIES INVOLVED

2.1 Introduction

As Pronk et al. [4] showed, one of the success factors of a collaborative research project is clarity regarding everyone's objectives, benefits and risks. This paper briefly discusses the interests of the parties as described in the introduction.

2.2 University

The benefits for the university can be found in various policy documents. Contract PhD candidates and their employers address research themes that are relevant to business and society. By initiating these joint projects the university satisfies both their research and knowledge valorisation efforts in developing, implementing and commercialising their knowledge [5]. The Dutch government also encourages cooperation between universities and industry. The government wants to increase the number of PhDs in business since they contribute to increasing the competitiveness of the country [6].

The interests of academic staff regarding contract PhDs differ. We interviewed four TU Delft professors who are supervising several contract PhDs for approximately one hour each. The semi-structured interviews were conducted using an interview template, and were recorded and transcribed. All transcripts were then analysed. Furthermore, in the past two years, we spoke with many researchers and professors about their experiences during and after various meetings: from informal one-to-one meetings with PhD candidates to official go/no-go meetings. In this paper, we focus on why the professors are interested in starting with a contract PhD and the problems they encounter during the various phases of the PhD project. We leave out of consideration the various ways they supervise these PhDs.

The manner in which university supervisors get involved in these collaborative PhD projects differs. A professor and PhD candidate may know each other for a longer time: 'It's someone from my network' or ‘It’s a former student’. It also happens that an organisation, for example the tax authorities, asks a university professor to conduct joint research on innovative ICT applications. The university professor may then select one or more PhD candidates from this organisation.

Although there are several reasons to collaborate, university professors tend to be mainly interested in PhD candidates who will contribute to their own research. The goal is to publish jointly in the scientific journals in which they themselves publish. The greatest advantage of contract PhD candidates is that they have direct access to cases and data. For more context-related research, the experience of the PhD candidates has been viewed as very important: 'The contract PhD candidate understands much better what is going on at major complex infrastructure projects than a recently graduated PhD candidate who has been at the university only.' The other side of the coin according to some scientists is that contract PhD candidates, due to their experience, do not always want to contribute to the core of their research. Furthermore, the supervision of a contract PhD can take a great deal of time. That also has to do with the fact that the quality of the PhD candidates – and thus the quality of the dissertations – varies significantly.

Contract PhD candidates may also contribute to education. They can give guest lectures in order to link theory and practice or supervise graduate students. In addition to these well-known forms of education, contract PhD candidates can be enablers of innovative teaching methods, for example through participation in living labs, MOOCs, sustainable business idea competitions and so on. This collaboration increases awareness of sustainable development among the next generation of students.

2.3 Private and public organisations

The best chance for success is when the parties already collaborate [7]. Pilots with collaborative PhD tracks could therefore be set up with companies and organisations already involved with the university. Public and private organisations participate in collaborative PhD projects for different reasons, since they have different goals and responsibilities. In this section, we concentrate on companies. It was possible to provide an overview of the benefits for some companies by consulting several representatives (mostly managers) from companies in various consortia.

Companies are currently experimenting with how they can shape and maintain their intellectual capital. It is important for companies to offer individual employees interesting opportunities in their career development. The company gets more motivated and better trained employees in return. A partnership with a university also means access to the academic world. The development of cutting-edge technology and the foresight knowledge of universities will make these companies able to strategically respond to future developments or, in other words, ‘co-create the future’. They can take advantage of the good name and reputation of the university, thus increasing the market value of the company. Furthermore, by participating in a PhD project, several regular students can also become involved (e.g. for their Master’s thesis), which can help to attract young talent. Managers, however, differ in expectations of the applicability of the results. They mainly appreciate three or four related studies with intermediate results instead of one large-scale study.

2.4 PhD candidates

We also studied the needs of PhD candidates employed elsewhere. Because their talents and expectations are at stake the most, we decided to elaborate in more detail on the needs of the PhD candidates.

Ten PhD candidates were interviewed for approximately 90 minutes each (see table 1). The semi-structured interviews were conducted using an interview template with seven blocks of questions. Each interview started with general questions about the motivation for, background to and subject of the PhD study. The second block contained questions concerning the educational programme. This was followed by blocks of questions about the problems they encountered during the first year, during the next phase and during the final phase of the PhD project. Finally, there were questions relating to external partners: what kind of support do you receive from your company? There were also questions about the future: what do you want to do with the end result, both in terms of career development and implementation of the results? The interviews were recorded and transcribed. All transcripts were then analysed using the seven blocks of questions. Respondents 7 to 10 were followed and interviewed several times during their first year. In this paper, we focus on the motivation to start a PhD project and the problems encountered during the various phases of the PhD project.

Table 1. Background of the respondents and their motivation to start a PhD

	Background (study)	**Background (work)**	**Motivation**
1	Information science, MBA	Employed at energy company	- Value for the enterprise - Personal development
2	Mechanical engineering, process technology in chemical engineering, executive MBA	Self-employed (formerly employed at [different] energy company)	- Academic career
3	MTS, HTS	Teacher at university of applied sciences	- Achievement of highest level on this topic
4	Electrical engineering	Teacher at university of applied sciences	- Interest in the topic
5	School for business administration and economics (in Dutch: HEAO), Master's in Information management, register accountant	Registered accountant at Dutch tax and customs administration, and trainer at a university	- Tax administration has opted for ICT research - Own motivation: more freedom and appreciation, higher level of teaching
6	Civil engineering	Staff/policy-making position at a water supply company	- Expert training, possibly to find a new job
7	Civil engineering	Project manager	- Achievement of highest level on this topic
8	Civil engineering and MBA	Self-employed (senior consultant)	- Intellectual challenge - Develop own ideas - Useful for company
9	Bachelor's in mechanical engineering, Master's in business administration	Project manager at design and engineering firm	- Validate scientifically what works of current activities
10	Internal relations (political science)	Innovation manager (energy company)	- Real contribution to discussion in society - Personal driver/ intellectual challenge

The motivation to do a PhD varies significantly, as table 1 depicts. All PhD candidates showed an interest in the topic and made an effort to change something essential in the current situation through their research. However, their ultimate goals vary, from a future academic career to innovation in their company or public organisation. In the case of two teachers at two different universities of applied sciences, it was less clear what they want to do with their PhDs; it might be self-evident that they use them in their teaching, but it could also be that too little attention is paid to the career prospects of teachers at universities of applied sciences with PhDs.

Success factors identified by the five first-year PhD candidates were: 1. quality of the supervisor; 2. flexibility to organise work; 3. substantive linkage PhD topic with work. What they described as difficult in their first year was: 1. finding the right scientific frameworks and getting it on paper; 2. continuous balance: work and PhD, practice and science; 3. administration around it.

A large part of the interviews was designed to create an overview of the problems encountered by PhDs or what they feel is lacking in the process. Some of these problems can be easily solved. Administrative problems and IT-related problems, for instance, can be solved through a proper intake process and by appointing someone who is responsible for organising an effective infrastructure.

This study, however, revealed other problems that are less easy to solve since they arise from differences between the domain of practice and that of scientific research. These PhD candidates work in a company (domain of practice), often for many years, and are motivated to solve a practical problem. They want to make a difference in practice through their research, which is another starting point that differs from an internal PhD candidate carrying out a subsidised project with a proposal written by a scientist. The translation of a practical problem into a scientifically interesting research question is a difficult issue for most contract PhD candidates. They use their own reference scheme to solve this issue, but that approach falls short. Some supervisors also speak a language different from what the PhD candidates are used to. In terms of the Model–Activity–Utility (MAU) framework, developed by Sjoer, Nørgaard and Goossens, universities and companies operate on the basis of different models, carrying out different activities. What is more, the incongruity regarding the production of satisfactory results poses problems for contract PhD candidates and universities [8].

3 OUTLINE FOR A COLLABORATIVE PHD TRACK

Collaborative PhD tracks that overcome these problems should be designed in such a way that they are consistent with the relationship and everyone's interest in it, as well as the needs and talents of the PhD candidate. This approach should lead to more successful doctoral education programmes. Based on the results of this study and the existing literature, a tailor-made track within the graduate school of the university was defined. We consider the first year of the PhD study in this paper.

There are several ways to get in touch with the university to arrange a PhD trajectory, and there are different paths to success. Candidates differ in backgrounds, motivation and skills. The route outlined below is therefore not a fixed but a flexible way to better support contract PhD candidates.

Preparatory phase
Every PhD candidate starts with an on-boarding module: ‘From Practice to Science’. The goal is for the candidate to discover what a PhD trajectory requires, what the differences are between the world of practice and that of science, and the language that goes with it, and to combine practical and scientific relevance towards an initial research proposition. Meeting other contract PhDs and exchanging experiences are

also part of this module. This module can be done online or blended, and results in a F2F presentation of a (written) research proposition. At this meeting, there are important points on which agreement should be sought:

a. Are all parties sufficiently interested and is the theme of sufficient strategic and scientific interest? The subject of the research should be interesting for all parties involved. This sounds obvious, but all parties (PhD candidate, organisation and university) should be committed to a topic for a longer period of time. So the topic should be the core business, or sufficiently related to the future core business, of the organisations involved.
b. Are all those concerned committed to carrying out or supervising this PhD research for a longer period, namely towards the go/no-go decision (after approximately 1–1.5 years and then after approximately a further 3–4 years)? All parties should be able to work together for a longer period of time. Continuity in the guidance team is a well-known success factor. A recommendation for all parties involved is to invest in the relationship and to pay attention to the selection criteria for all supervisors. For instance, selection criteria for the company supervisor might be the ability to contribute to the implementation of the results and a knowledge level on the specific topic that is roughly in the same range as that of the allocated university supervisor (cognitive proximity) [9]. On the side of the university, we observed that many PhD candidates prefer to be supervised by professors they already know; however, other professors might be more appropriate.
c. Are the expectations, wishes and conditions of the company supervisor, the university supervisors and the candidate discussed satisfactorily? Topics such as time allocation, funding, guidance, intellectual property rights, and publications need to be agreed upon. As stated by Salimi [10], the success of a collaborative PhD project is more likely if there is joint decision-making, which is more often the case when there are mutual dependencies. That means that no one party controls all critical resources.

As a result of this meeting an agreement should be signed and the candidate should be registered at the graduate school as a PhD candidate.

First year

At the start of a doctoral education programme, a short introduction module will be assembled in consultation with the PhD candidate. Many compulsory start-up modules at graduate schools are designed for a different target group and are done at times that are not suitable for part-time PhDs. Further, a workplace with ICT facilities, a library card, etc. is provided by the faculty of the PhD candidate. Moreover, the candidate will be invited to join the scientific community related to his/her topic. It is recommended to see whether several collaborative PhD projects can reinforce each other. The projects contribute to the same body of knowledge and, although PhD candidates run their own projects, they could meet, share insights and stimulate each other.

The graduate school of TU Delft has an extended doctoral education (DE) programme. The DE skills training programme offers a range of courses and activities that help candidates to acquire transferable skills, increase their disciplinary competences and obtain research skills. In the guidance team of the contract PhD candidate, training needs should be discussed. Nearly all PhDs examined are especially in need of research-related skills. They follow courses such as The informed researcher (at the library), Research design and, if relevant ‘How to make a questionnaire and conduct an interview' and 'Discovering statistics using SPSS'. Additionally, 'Scientific writing in English' courses are popular. The knowledge acquired in the courses should be applied immediately in their own research, which is often part of the course design; however, it also requires on-the-job coaching afterwards. For the courses to teach discipline-related skills or transferable skills, customisation is needed since the offerings are not tailored to this target group. Therefore, the process of getting a PhD and the needs and talents of the candidate should be discussed regularly. HRM plays a role in this.

Many graduate schools and doctoral education programmes have a form of performance assessment in place. At TU Delft, the products for the go/no-go decision point after 12–15 months usually consist of a research proposal and/or a first article. It seems best to structure a collaborative PhD track according to a set number of scientific articles. In this way, progress is made visible and there is always something to celebrate. In addition, it fits the rhythm of engineers, who often work in successive projects. Further, the extent to which the cooperation runs smoothly can be assessed. Most contract PhDs are goal oriented. They want to know the precise requirements for the deliverables for the go/no-go meeting and they make a detailed plan of how to get there.

Not all PhD candidates, however, survive their first year. As literature shows, there are several reasons why doctoral candidates drop out: they either do not come up with a concrete research question or they receive inadequate guidance [11]. Yet, for contract PhDs there are some other pitfalls such as their unrealistic expectations (over- or underestimation), not being taken seriously as PhD candidates, little physical presence so that they become 'invisible' and socially isolated. In all cases, guiding a contract PhD is guiding a 'transition' in identity development [12]. We believe that the aforementioned ingredients of a collaborative PhD track strongly support contract PhDs and their companies in overcoming these problems.

4 CONCLUSION AND RECOMMENDATIONS

This paper answers the question what does doctoral engineering education for contract PhDs look like in order to run smoothly and fulfil the promise of sustainable development. By interviewing stakeholders (PhD candidates, university supervisors and company supervisors), observing several collaborations, consulting literature and performing a benchmark with other university programmes, we identified requirements for a collaborative PhD track within a graduate school. We identified 10 recommendations to better train an experienced engineer in becoming a scientific researcher while at the same time facilitating a collaborative project in which new knowledge is developed that should lead to innovation.

1. Set up the collaborative PhD track as a multi-year collaboration between the PhD candidate, the employer of the PhD candidate and the university.
2. Introduce a preparatory phase. One of the most difficult issues for contract PhDs is the transformation of the world of practice into the world of science. Important questions for an engineer who has been away from university for quite some time are: what are the scientific frameworks, which language fits with it and what makes a topic scientifically interesting? This phase ends with the presentation of a written research proposition that is interesting for all parties involved.
3. Discuss expectations and formalise commitment with the employer of the PhD candidate before starting a PhD trajectory.

4. Offer an introductory programme in consultation with the candidate instead of a compulsory programme at inconvenient times. This approach is critical to setting a tone of flexibility and enabling rather than standardisation and bureaucratising.
5. Create a tailor-made educational programme. The actual educational needs should be defined. The focus should be on what is really necessary for this PhD candidate to become a good scientist, not on obtaining all kinds of exemptions. It appears that mainly research-related skills are important. Time, attention and credits should be based on what is needed.
6. Ensure that administrative and ICT-related issues are well organised and not time consuming. Many candidates from industry are used to a well-organised infrastructure in which they receive good support.
7. Facilitate relationships between contract PhDs themselves and between contract PhDs and their scientific peers. It is important to ensure that this PhD trajectory is not a lonely journey, but a joint effort in a learning community that pays off for all parties.
8. Better prepare academic staff, since adult learners' needs differ from those of regular students. Furthermore, collaborating in a multidisciplinary PhD track is not always easy. It requires specific training expertise and 21st-century skills that cannot be transferred through an information meeting, but requires forms of coaching and peer review, or more unusual arrangements such as job rotation. For example, a daily supervisor can work for a certain period of time in a company, and the PhD candidate can provide regular education.
9. Assign a dedicated person for collaborative PhD candidates within the graduate school.
10. Ensure a link between the subject of the PhD candidate and the strategic needs of the company of the PhD candidate; It increases the chance of success substantially.

A collaborative PhD track can be valued as a multi-year collaboration between PhD candidate, employer and university, with an explicit commitment for a longer period of time. In these tracks, the flow of academic expertise into practical application is accelerated and the promise of sustainable development can be realised. The focus is not only on the best practice, but also on 'the next practice'. And above all, collaborative PhD tracks ensure an interesting learning process for all parties involved.

ABSTRACT

Global changes in technology and culture have drastically altered the needs of industry and society and thus the graduate engineering workforce required to fulfil those needs. With access to the whole body of human knowledge at the touch of a fingertip, learning is moving away from merely accumulating a body of facts. Instead, future engineering graduates need skills in assimilating and applying knowledge, thinking creatively, working collaboratively and in being agile and embracing change. As the mind-sets, skill-sets and knowledge-sets needed by engineering graduates shift, so too must higher education curricula, shifting to an experience-based curriculum that stimulates students to develop personal qualities and professional skills alongside the specialist knowledge of their field. Authentic, relevant student experiences that give engineering students employable skills cannot be created in isolation in universities thus a new curriculum is needed, to be co-designed with employers, industry experts, professional bodies and education specialists. This paper describes efforts underway to develop a new engineering curriculum with industry-led and project-based learning experiences running throughout the course and will propose a model for the co-design of this curriculum with industry and other key stakeholders.

Conference Key Areas: Curriculum Development, University-Business cooperation, Skills and Engineering Education

Keywords: Curriculum, Work-integrated learning, Industry, Project-based learning

INTRODUCTION

Global changes in technology and culture have drastically altered the requirements of industry and society and thus the graduate engineering workforce required to fulfil those needs. With access to the whole body of human knowledge at the touch of a fingertip, learning is moving away from merely accumulating a body of facts. Instead, future engineering graduates need skills in assimilating and applying knowledge, in thinking creatively and collaboratively, in being agile and embracing change in a rapidly transforming world. Many studies and reports have called for a new approach to engineering education (e.g. Beanland and Hadgraft [1] and King [2]), indicating that different types of engineers are needed in 21st century engineering practice. Being able to synthesise information to solve problems and create solutions has become far more important than the ability to remember facts. The ability to understand diverse consumer needs and communicate in many ways with diverse stakeholders is key to working in a global market.

Research in engineering education has seen some changing trends with the increased application of project-based learning, team work, flipped classrooms, use of open online resources, and more authentic assessment practices. Work-integrated learning opportunities, along with study tours and service learning projects, are also becoming more widely valued. However, many changes are incremental and often project and team work, study tours or placements are either optional extras or bolt-ons that are experienced once by the student but not integrated into the curriculum of the wider degree program.

Though most, if not all, accreditation bodies include professional skills as a crucial part of their accreditation processes [3-5], there has been a conflict between the growing awareness that engineers need to possess a wide array of personal and professional skills and the perceived need to cover in depth all of the increasing technical content [6]. Professional skills such as communication, teamwork and ethics are also often perceived as difficult to teach and assess, though there are many examples of how these skills can be taught if explicitly targeted (see Shuman, Besterfield-Sacre [7] for a comprehensive overview).

A recent report by the Australian Council of Engineering Deans made a series of six recommendations to ensure engineering schools can meet the country's future need for engineers, one of which was for "educators and industry practitioners to engage more intensively to strengthen the authenticity of engineering students' education" with "more effective and increasing input from industry practitioners to engineering schools in the processes of setting, reviewing and tracking attainment of graduate outcomes" [2]. Authentic and relevant student experiences that develop professional skills in engineering students cannot be created in isolation in universities. For true work-integrated learning a new curriculum is needed, including experiences that must be co-designed with employers, industry experts, professional bodies and education specialists. Engineering practitioners and employers are best placed to identify the tasks that engineering graduates will be faced with and the knowledge-sets, skill-sets and mind-sets they need to accomplish those tasks.

This paper outlines a framework for co-designing a new engineering curriculum with industry, moving away from a content-driven curriculum and towards an approach aimed at developing professional skill-sets and mind-sets. Though this work is undertaken in an engineering context within Swinburne University's Engineering Practice Academy, it is with the aim that the consultative curriculum co-design process will be applicable to other discipline areas in higher education.

THE CONSULTATIVE CURRICULUM DESIGN PROCESS

1.1 Overview

An overview of the curriculum design process is presented in Figure 1. The curriculum co-design requires input from a range of stakeholders which is fed into an iterative development process under the overarching goal of developing graduates with skills allowing them to work as the engineers of the future. The proposed course requires an experience-based rather than a content-focused curriculum with the objective that the engineers graduating from the course must be employable. Employability is defined by Yorke [8] as having “skills, understandings and personal attributes – that makes graduates more likely to gain employment and be successful in their chosen occupations, which benefits themselves, the workforce, the community and the economy.”

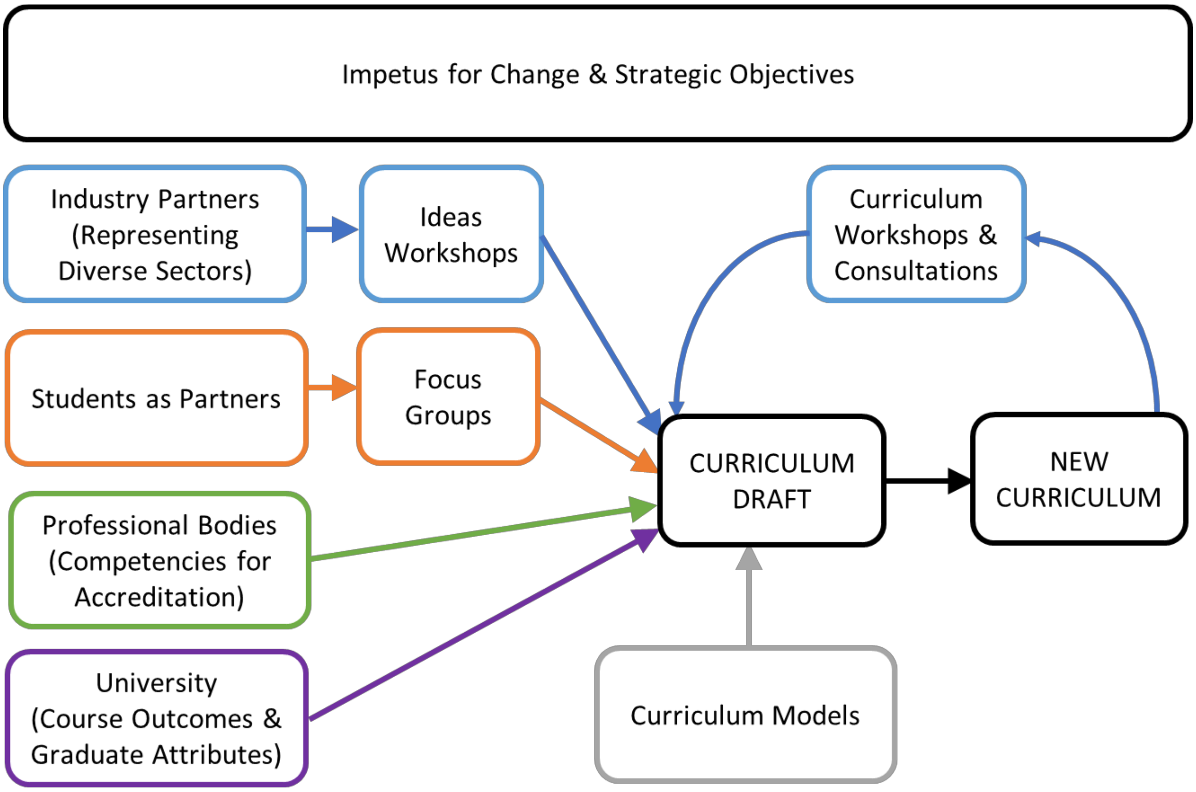

Fig. 1. Framework for consultative curriculum co-design

The structure was adapted from the “Design your Discipline (DYD)” stakeholder consultation process [9] which was created to facilitate curriculum renewal in undergraduate programs. In the DYD process consultation takes three forms: “stakeholder consultation” to gather a full range of views from diverse stakeholders, “consensus building” to come to an agreed position and “engagement for change” to engage stakeholders in future change processes. Engagement for change is particularly important in this case as the industry partners being consulted are also being sought as partners in the delivery and assessment of the future course and their input will ideally be ongoing. The aim of engaging industry partners in the creation of the curriculum at all stages is both to benefit from their expertise and give them a sense of ownership of the program being developed.

Current engineering students have also been consulted as part of the process and it is the intention to involve future cohorts of students in the shaping of the curriculum and other aspects of the course. ‘Students as partners’ is a growing field of study in the education community and has emerged from international acknowledgement that new approaches are needed to engage students in their learning [10]. The UK Higher Education Academy (HEA) has published a framework for engaging students as partners based on dozens of documented case studies, one outcome of which is the advocacy of student partnership in curriculum design and pedagogic consultancy [11]. This paper however focuses on consultation with industry; forthcoming papers will describe the consultation process with students.

Close consultation with relevant professional bodies is also necessary. Engineering Australia (EA), as the professional body responsible for accrediting engineering programs, was consulted. The EA Stage 1 competency standards for Professional Engineers (the competencies deemed necessary for entry to practice corresponding to an accredited 4-year Bachelor or 5-year Masters degree) were used as a guiding input to the curriculum design. The specific university course objectives and graduate attributes for current engineering courses, which were developed from and closely linked to the EA competencies, were also used alongside broader university-wide values and goals.

1.2 Ideas Workshops

Potential partners were identified by the University collaborations and partnerships team, leveraging existing research connections and seeking new partnerships. The aim was to connect with a range of partners spanning as broad a range of organisations as possible spanning, for example defence, mining, not-for-profits, spanning small local businesses to large multinational corporations. Sixty-six individuals from fifty organisations participated in three workshops, split between on-campus and external venues, and morning and afternoon time slots, so participation was not limited by geography or scheduling.

The workshops included a presentation about the vision of the project but the main focus was not on telling the participants what was being planned, but asking them for their input. The key messages were that anything was possible and that genuine collaboration was integral to the whole enterprise.

The bulk of the workshop consisted of three micro-sessions where questions were posed and discussed by the industry participants in mixed groupings, consisting of participants representing diverse industries to encourage varied viewpoints. Notes were taken by project members and groups fed back to the wider workshop, with common themes emerging, but some groups providing unique insights.

The themes of the micro-sessions were:

- Emerging industries and industry trends
- Skill-sets and mind-sets required of graduates
- Tasks performed by graduates

The notes were then transcribed and coded to identify key themes and the frequency with which they were mentioned. Many of the themes occurred across all the micro-session discussions, for example “interdisciplinarity” and “working globally”. The data on emerging industries and trends was used to inform the creation of new specialisms and aspects of the discipline-specific curriculum and are not discussed further in this paper. The data on the professional skills and personal traits required by engineers were used to inform the next stage of the curriculum design process. A summary of the outcomes of the workshops was also circulated to all industry participants.

1.3 Analysis and framing

Information about the skills required of the engineering graduates of the future gathered from the ideas workshops was combined and compared with Engineers Australia's Stage 1 Competencies and the university's own stated Engineering Competencies as well as considering more general competencies such as Lominger's 67 competencies to measure a person's effectiveness in business [12].

These were grouped by the authors who debated the structure and links between the skills and organised them into common themes. Innovative curriculum and learning models (e.g. Thinking Like and Engineer [13] and Vitae [14]) and other conceptual frameworks for categorising competencies such as constellations and multidimensional representations [15] were used as examples of how to organise and structure skills into a curriculum framework. Once a curriculum framework was agreed on, the skills and competencies identified from the ideas workshops and other sources were mapped to the framework to form a draft curriculum.

1.4 Curriculum development workshops

A total of 21 participants from 18 organisations took part in the second set of workshops. Most participants had been involved in the ideas workshops but 6 were new participants. The format was similar to the previous workshops, with the initial presentation explaining the current curriculum draft and the facilitated group work involving discussion around the draft with feedback presented by group members. The questions industry participants were asked to focus on were:

- Sense check/ communicative validity – the new skills curriculum is very different from traditional content focused curriculum. Does it make sense?
- Are there any skills missing or requiring more emphasis?
- How could this framework be used to describe graduates given it is very different from a transcript listing grades and subject areas?

The draft curriculum was updated after the first workshop and the second draft dissected by participants during the second workshop. The process of co-designing a curriculum with industry partners is necessarily iterative and can be repeated as many times as needed until the additions to the curriculum are negligible. Individual consultations with industry partners on specific aspects are also useful at this stage, to further break down particular curriculum points.

1.5 Draft curriculum

The draft curriculum is presented in figure 2. It consists of four domains, each of which is divided into three sub-domains.

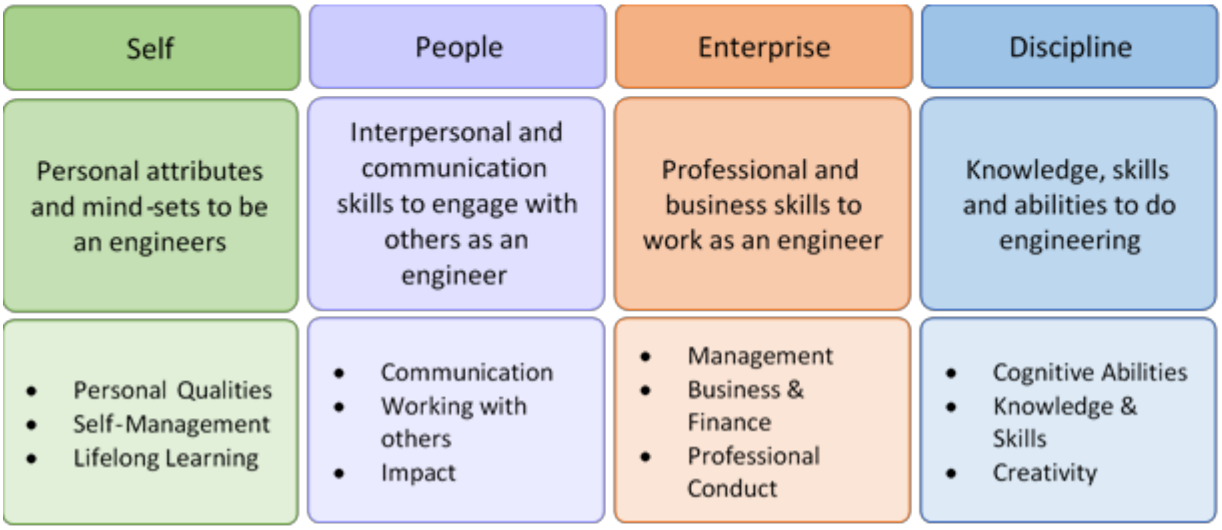

Fig. 2. The domains and sub-domains if the draft curriculum.

2 REFLECTION

Industrial partner buy-in and enthusiasm are key, and so far have been extremely high. From the very first ideas workshops, industry participants were using language such as “we” when discussing the creation of the new course and in later workshops participants discussed having actively promoted the new curriculum ideas in their organisations and with external clients.

The draft curriculum, with a much greater focus on professional skills and personal attributes than in traditional programs, seems to have resonated with workshop participants, with for example one industry partner summarising this as “I hire a person, not a position”. This is consistent with results from the literature where attitudinal and non-technical competencies have been rated as just as if not more important than technical knowledge [16].

The areas of the curriculum that industry partners particularly contributed to in the curriculum development stage were around business and enterprise and the knowledge and skills graduates would need in this area. They also contributed to expanding on the self-management, career literacy and creativity skills that graduates would require. In areas such as communication and disciplinary knowledge the model was validated but not much expanded upon after the initial ideas workshop.

There are several areas for further study that have emerged from the curriculum design workshops. One repeated theme in the early ideas workshops was that of “the fundamentals”, with industry participants adamant that these still be taught without a clear explanation of what this meant, and without clarity as to whether participants from different industry sectors all considered the fundamentals to be the same knowledge set. This requires further investigation as to what fundamental maths, science, or other engineering knowledge is required by modern engineers, as opposed to what is expected to be taught based on an adherence to what has been taught in the past.

Another area of investigation is how to present the outcomes of this curriculum model in a form that can be understood by employers in the manner of a transcript. This is an important concern as a key goal of this new degree is to increase employability, and any improvements in graduate skills are moot if these skills cannot be communicated clearly to potential employers. More than just listing the competencies graduates will have demonstrated, there will also need to be a way to differentiate between students and elucidate in which curriculum areas they have developed specific depth.

An interesting aspect of this process of co-designing a curriculum with industry participation is how quickly ideas and language develop. Initial curriculum discussions among the academics were based around a skills triad of knowledge sets, skill-sets and mind-sets. After the ideas workshops it rapidly became apparent that four categories were required, with skill sets subdividing into business & enterprise skills and communication & interpersonal skills, each of which were deemed sufficiently crucial and broad in terms of sub-themes to warrant separate consideration. The language also evolved, for example from initially talking about 'mind-sets' during the consultation process to subsequently using terminology such as 'self' and 'personal attributes'. This continual development of language and ways of thinking is a sign that the co-design is more than a token consultation, but is a true co-construction of ideas.

Another interesting aspect of the process is how it can be applied in many areas beyond engineering. This is both in terms of the transferability of this framework to other disciplines, indeed it is designed to become part of a wider university strategy, but also in terms of the curriculum developed. The curriculum, while containing some aspects unique to engineering practice, is primarily comprised of competencies that apply to many if not all fields of study in higher education.

3 CONCLUSION

A rapidly changing world requires engineers with different skills sets and thus radically different engineering degrees to prepare them for the workplace. This paper has proposed a framework for co-designing the curriculum for such a degree with industry partners, ensuring its relevance in the workplace and the employability of graduates from such a program. The process has been embraced by industry partners who have contributed enthusiastically to the initial ideas workshops and by providing insights into subsequent draft versions of the curriculum. The process is ongoing, both in terms of the academic-industry collaboration in developing the curriculum but also beyond into industry partners being involved in the setting, delivery and assessment of student projects. Future work will involve establishing frameworks for this continued collaboration as well as expanding on aspects of the curriculum such as "fundamental knowledge" and investigating how such a revolutionary curriculum can be presented to potential employers in terms of explaining graduate capabilities. Overall, the process of co-designing the curriculum has been one of true collaboration that has been positively received by industry partners and is the first step in creating an engineering degree with high levels of industry engagement leading to highly employable graduates.

ABSTRACT

The article is focused on continuing professional development (CPD) of engineers and technical professionals in Russia supported by the Government and its influence on the development of engineering education. Specifically, it explores a case of Tomsk Polytechnic University (TPU) that took part in the Presidential programme for advanced training of engineering personnel (2012–2014) and in the Departmental special-purpose programme aimed at professional development of engineers and technicians (2015–2016). The study incorporates a mix of quantitative and qualitative methods that helped define the common features of engineering CPD programmes and provided insights into the contribution of such programmes to the development of engineering education and university-industry collaboration. In particular, according to the study results the delivery of government supported CPD programmes for engineers encouraged the engagement of industrial companies in development and delivery of bachelor's and master's degree engineering educational programmes. The TPU experience is a good example for development of university-industry strategic partnership that might result in a higher quality of engineering education.

Conference Key Areas: Continuing Engineering Education and Lifelong Learning, Engineering Skills, Sustainability and Engineering Education

INTRODUCTION

Continuing professional development (CPD) of engineers and technical professionals is an essential factor for the development of human capital which tends to have a great impact on industry evolution and economic growth. The ability to be engaged in independent lifelong learning and to undertake CPD activities sufficient to maintain and extend his or her competence is considered to be one of the key professional engineer's competences [1–5]. Traditionally, continuing engineering courses include in-house training and courses offered by educational institutions, private organizations or professional communities and associations (see e.g. Engineers Ireland, Engineers Australia). In Japan, continuing engineering education in enterprises and research organizations is widespread [6], whereas in other countries the universities continue to be the preferred CPD provider while they combine research, innovation and education [7, 8]. The involvement in engineering CPD is a challenging task for the universities and it requires an active interaction between the university and the company during development, delivery and evaluation of CPD courses [9].The European bodies such as the European Society for Engineering Education (SEFI) and the European Federation of National Engineering Associations (FEANI) are working in the field of engineering CPD, they set CPD policy and guidelines as well as provide methodological support and launch some relevant projects and studies in the field.

The formation of highly qualified engineering personnel belongs to the strategic objectives of the Russian Government. In 2012, the Executive Order On the 2012–2014 Presidential programme for advanced training of engineering personnel was signed. The programme aimed at professional development of engineering personnel working in the strategic industries as well as at modernization of engineering education in the context of strategic partnership of Russian educational institutions and industrial companies. In 2015, it was decided to launch the similar Departmental special-purpose programme aimed at support and promotion of the best practices in engineering CPD.

1 DEPARTMENTAL SPECIAL-PURPOSE PROGRAMME "ADVANCED TRAINING OF ENGINEERING PERSONNEL IN THE YEARS 2015–2016"

1.1 Programme description

The Departmental special-purpose programme "Advanced training of engineering personnel in the years 2015-2016" was launched by the Order of the Ministry of Education and Science of the Russian Federation in May 2015 [10]. The programme is aimed at support and promotion of the best CPD courses for engineers and technicians in the priority areas of science and technology in the Russian Federation including nanosystem industry, information and telecommunication systems, life sciences, sustainable use of natural resources, transport and space systems, energy efficiency, power saving, nuclear power engineering, etc. The programme goal is to increase the contribution of educational institutions to the development of human resources in strategic industry fields that might stipulate technological modernization of economy, increase in labour productivity, and creation of highly productive jobs.

The objectives of the programme include the development of public-private partnership by professional development of engineering personnel and modernization of content and educational technologies of engineering CPD courses. The training courses that take part in the programme must be developed by Russian educational institutions in collaboration with targeted enterprises and industrial companies, which have to provide no less than 50% co-funding. Besides engineers, there are master's degree and post-graduate students, as well as engineering educators among the trainees.

The programme incorporates the concept of the Triple Helix of university-industry-government relationships proposed by Etzkowitz [11]. The universities develop and deliver engineering CPD courses in strong collaboration with industry companies to develop human resources of engineering enterprises and this process is supported by the government and industrial companies. All the participants of this process have got their benefits: the government gets highly qualified engineering personnel and economic growth as a consequence; the universities develop the relationships with industry followed by an active engagement of employers in their activities; the industry companies can reduce expenses on staff professional development by sending the employees to the government supported CPD courses chosen in competitive selection process.

1.2 Programme results

The competitive selection of CPD courses for engineering personnel organised by the Ministry of Education and Science of the Russian Federation allowed choosing 385 professional training courses for engineers and technicians offered by 82 educational institutions. Over 8000 engineers and technicians employed by 751 industrial companies took part in these courses. Under the terms of the programme no less than 20% of trainees (1804 persons) went on on-the-job training on the premises of Russian industrial companies and engineering centers, no less than 10% (979 persons) went on practical training on the premises of industrial companies and engineering centers abroad in 38 countries [10].

The feedback results gathered from CPD courses' graduates show that 96% of respondents point out, that the competencies developed during the training courses are highly relevant for their professional activity. About 90% of industrial companies recognize that this government supported programme has contributed a lot to improvement of the company effectiveness [12].

One of the important results of the Departmental special-purpose programme "Advanced training of engineering personnel in the years 2015-2016" is the creation of the engineering CPD courses' pool incorporating the best practices of vocational education and training courses (see http://engineer-cadry.ru/).

2 GOVERNMENT SUPPORTED CPD COURSES FOR ENGINEERS: TPU CASE

2.1 Course development and delivery

Tomsk Polytechnic University (TPU), one of the leading engineering universities in Russia took part in the Departmental special-purpose programme "Advanced training of engineering personnel in the years 2015-2016" as well as in the 2012–2014 Presidential programme for advanced training of engineering personnel. As a result of the competitive selection in the frameworks of these programmes TPU gained the right to deliver about 40 CPD courses. More than 700 engineers and technicians from 125 Russian industrial companies were trained (see *Table 1*).

Table 1. Results of the government supported programmes aimed at the advanced training of engineering personnel: TPU experience

Year	Number of programmes	Number of trainees	Number of companies
2012	4	117	23
2013	10	187	27
2014	9	135	25
2015	6	90	12
2016	12	197	38
Total	**41**	**726**	**125**

In 2016 TPU gained the right to deliver 12 CPD training courses for engineering personnel, it was the best result among the Russian universities that took part in the competitive selection. The high quality of TPU courses was recognized, their common features are described below.

1) ***Targeted course design.*** The collaboration between a university and a company is critical in the establishment of an effective framework for professional development [9]. The intended learning outcomes of each CPD course offered by TPU were developed based on stakeholder needs and requirements of correspondent professional standards. The outcome-based approach helped develop in-demand training courses, which graduates demonstrate professional and general (non-technical) competencies relevant for a particular industry field.

2) ***Adoption of the best practices in engineering education.*** Being the member of leading international organizations and initiatives dealing with engineering education including SEFI, IGIP, CDIO Initiative, etc., TPU adopts and implements modern teaching and learning approaches. The university has developed a coherent CPD system aimed at the development of faculty competencies [13]. The system combines over 40 training programmes that contribute to the development of key faculty competencies such as ability to design, deliver and evaluate educational programmes in compliance with national and international standards, ability to use various educational technologies and active learning methods, ability to conduct students' project and research work, etc. Besides, there is a list of programmes aimed at the development of specialized faculty competencies connected with design, implementation and operation of engineering products, systems and technologies.

   The CPD courses for engineering personnel offered by TPU are delivered using collaborative learning, problem-based learning, project work, integrated learning experience, e-learning technologies (some courses are supported by e-courses in LMS Moodle). Each course consists of lectures and practical studies in university premises (more than 72 h), internship in Russian leading industry companies and engineering centers (to 50% of trainees), and internship abroad (to 30% of trainees). The trainees develop professional theoretical skills in addition to the practical work skills; they also gain the experience of working abroad in an international team which is very important in the process of internationalization of engineering profession.

3) ***Facilities and equipment.*** The CPD courses are provided with engineering workspaces, laboratories and modern equipment to emphasize hands-on

learning. TPU has a few authorised centers (Hughes-TPU Center, SolidWorks Authorised Training Center, Accreditation, Monitoring and Diagnostics Regional Center, etc.). The created learning environments allow developing practical engineering skills (see CDIO engineering workspaces [14]).

4) ***Strategic partnership.*** TPU has a well-developed network of contacts with Russian and foreign industrial companies, research and engineering centers. It helped find partner for development and delivery of CPD courses for engineering personnel to provide on-the-job training and internships in Russia and abroad.

2.2 Findings and interpretation

The results of a questionnaire delivered to the industrial companies which employees took part in the TPU professional training courses show their positive attitude towards these government supported CPD programmes. The main results are the following:

- 70% recognize the need for lifelong learning.
- 67% are ready to take part in TPU career events for students and graduates.
- 67% have a wish to be involved in students' job-placement.
- 56% want to make some research projects in cooperation with TPU.

All the respondents expressed a wish to be engaged in development, delivery of engineering educational programmes and assessment of learning outcomes. It is a crucial result in the context of quality assurance of engineering educational programmes, as according to the accreditation criteria of the Association for Engineering Education of Russia (AEER) used for educational programmes in engineering and technology, the employers as the main stakeholders have to take part in the definition of learning goals and intended learning outcomes, as well as in the evaluation of programme graduates [15].

The companies' representatives highlighted in their interviews that the government supported CPD courses helped save financial expenses for the professional development of their staff. They also pointed out a high quality of methodological support and qualification of faculty members engaged in training courses. They confirmed that the engineering CPD courses offered by TPU are in full correspondence with current industry needs.

These results demonstrate that delivery of government supported CDP courses for engineers and technicians has a positive impact on both industry companies and educational institutions as well as on the development of industry-university collaboration.

3 SUMMARY

The development of human capital is a crucial aspect for economic growth of any country. The government supported programmes for advanced training of engineers and technical professionals realized in Russia in 2012-2016 could be a good example of public-private partnership by professional development of engineering personnel. The case of Tomsk polytechnic university shows that these programmes have a positive influence on the development of engineering education. In particular, they contribute to the engagement of industry representatives in design and delivery of engineering educational programmes. The companies which employees took part in CPD courses offered by TPU expressed a strong wish to develop partnership with the university.

ABSTRACT

Competitiveness, quality and sustainability critically determine the viability of enterprises on both sides of the Atlantic and around the world. Today's technologically advanced age requires systematic research and development – not the abstract theory-focused research so typical of university, basic and PhD research – but rather the use-inspired, agile and practically-focused research called for in *Pasteur's Quadrant* [1] and more recently the Swiss National Science Foundation [2]. The paper presents a model for a *professional doctorate* program that develops leaders with such skills at the very highest end of this capability spectrum. Such individuals are in demand, particularly by high-tech industries operating at new intersections of technologies. The program is delivered by a hybrid fusion of distance- and campus-based learning technologies and it is focused on enhancing the effectiveness of industry and other enterprises by providing high-performance leaders possessing a significant technological R&D skill set and inclination. The authors see the professional doctorate as essential to any nation seeking to evolve Industry 4.0 [4]. Our concept draws upon the experiences of colleagues in Europe, Australia and in North America and is enhanced by lessons from American entrepreneurship, innovation and distance learning.

University-Business cooperation

INTRODUCTION

This paper presents a work in progress, namely a model for a professional doctoral program designed to meet the current and future needs of contemporary European, North American and Asian business and industry for people with a high level of technology research and development skills and leadership strengths. In particular, the R&D personnel needed to fuel Industry 4.0 are addressed by this program. The paper is organized in three major sections beginning with an Introduction that highlights the core of the need and rationale for the program. Subsequently in section 1 the model for the program is described and in section 2 an implementation plan is presented. The paper's third section shares the authors' conclusions and envisioned next steps.

Clearly competitiveness, efficiency, quality and sustainability are critically important and increasingly interrelated characteristics that determine the future viability of enterprise on both sides of the Atlantic and in fact around the world. These characteristics require systematic research and development – but not the abstract theory-focused research that is so typical of university, basic, and PhD research – but rather the use-inspired, agile and practically-focused research called for in *Pasteur's Quadrant* [1] and more recently the Swiss National Science Foundation [2]. Fraunhofer IAO's Gelec & Wagner [3] noted in particular the increasing need for, and importance of, highly skilled R&D personnel as a major conclusion of their 162 advanced industry study. Clearly these such people will be instrumental in achieving the aspirations associated with Industry 4.0 and, because of their need to understand and have systems level competencies with technology, it is exactly the engineering and technology programs that SEFI encompasses that will have major responsibility in supplying such personnel.

But, where do the people come from who have such skills and inclinations? Particularly those at the very highest end of this capability spectrum? These are the individuals who are most in demand--particularly by high-tech industries -- many of which operate at new intersections of technologies, and/or disciplines, previously thought unrelated.

This paper presents a design for a professional doctorate in technology that will be delivered via a hybrid fusion of distance- and campus- based learning technologies. The program is focused on enhancing the effectiveness of industry, business and other enterprises by providing high-performance leaders armed with a significant technological R&D skill set and motivation to innovate. Importantly, an implementation plan that offers applicability to other institutions around the world is also presented in the paper.

The authors see the professional doctorate as essential to nations seeking to evolve Industry 4.0 [4] because such a doctorate is a flagship strategy for developing the critically needed cohort of technologically capable leaders. Our concept draws upon the experiences of colleagues in Europe, Australia and in North America, enhanced by lessons drawn from American entrepreneurship, innovation and distance learning. For example, Maxwell [5] reported on the rise of this kind of doctoral degree in Australia, New Zealand, England, the Netherlands, and Canada. They encompass disciplines in Business, Design, Technology, Engineering, Industrial Technology, and Engineering Science. In addition, Doctorates of Professional Studies exist in a further variety of fields ranging from Bioethics to Nursing. According to Zusman [6] by 2013 there were professional practice doctorates in at least a dozen fields in the U.S. with “more than 10,000 degrees awarded just in 2011-12 and roughly 35,000-40,000 students enrolled. (p.1)”

1 WHAT IS A PROFESSIONAL DOCTORATE?

The authors concur with Kot & Hendel [7] that currently, there exists no singular, widely accepted, and formally approved, definition of the professional doctorate. We have, however, noted, based on a synthesis of what European, Australian, and North American thought leaders and early deployers of such programs consider as the core tenets and essential characteristics of professional doctoral programs, that such degrees share enough commonalities to enable formulation of a way forward. In an initial exploration of the concept the authors [8] found that:

> Simply put, professional doctorates focus on in-depth, cutting-edge technologies, innovation skills and the leadership and effective organization of teams and corporate units. Such programs seek to prepare advanced level practitioners for business and industry rather than basic researchers for the academy. The goal is enabling increased competitiveness, sustainability and socially responsible endeavor. (p.27).

Insight as to the nature of a professional doctorate can be derived by comparing it to the characteristics of the traditional research-based Ph.D. Table 1 (on the following page) presents a detailed analysis of similarities and differences with respect to 19 key attributes as adapted from Bourner et al. [9]

In addition to the design characteristics highlighted by Bourner, in the American context, it is of critical importance that the Purdue University Polytechnic Institute’s program meets the US Government’s requirement to be recognized as a doctoral level degree. The US Department of Education’s Integrated Postsecondary Education Data System (NCES, n.d.) (IPEDS) classifies “Doctor's degree-professional practice” as follows [10]:

> A doctor's degree that is conferred upon completion of a program providing the knowledge and skills for the recognition, credential, or license required for professional practice. The degree is awarded after a period of study such that the total time to the degree, including both pre-professional and professional preparation, equals at least six full-time equivalent academic years.

Because of this requirement, and as depicted in Figure 1, the Polytechnic Institute’s professional doctorate program was designed to build upon a master’s degree and consequently the doctorate is structured to enable completion in 2-3 years or as determined by the student’s intensity of pursuit.

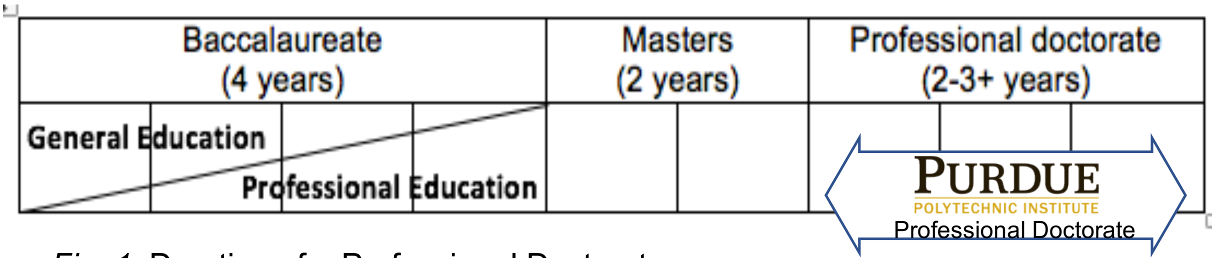

Fig. 1. Duration of a Professional Doctorate

Table 1. Professional vs. Research Doctorates [9] (p.30)

Attribute	Academic Ph.D.	Professional Doctorate
1. **Career focus**	Entry into academia	Professional doctorates nearly always claim to address the career needs of aspiring professionals
2. **Domain of research topic**	Disciplinary theory	Professional practice
3. **Research type**	'original investigation undertaken to gain new knowledge and understanding but not necessarily directed towards any practical aim or application' (p. 71)	Issues of real interest to the profession
4. **Research focus**	A perceived gap in the literature	A problem encountered in practice
5. **Starting point**	Finding what is known in the literature	A problem for which the solution is unknown
6. **Intended learning outcomes**	Contribution to the literature	'A significant original contribution to knowledge of • professional practice through research, plus one or more of the following: • personal development (often specifying reflective practice); • professional level knowledge of the broad field of study; • understanding of professionalism in the field; • appreciation of the contribution of research to the work of senior professional practitioners.' (p. 72)
7. **Entry qualification & degree**	Undergraduate degree with high marks	A Master's degree is often required
8. **Experience as admissions requirement**	None	1-5 years usually expected, with a median of 3
9. **Taught component**	Minimal, under the "traditional Ph.D. model"	Ranges from 15 to 50% of degree requirement
10. **Modularity**	Relatively unstructured according to the "traditional Ph.D." model	Modular course and credit structure
11. **In-service vs. Pre-service**	Pre-service for research career	In-service for professional career, often taken while working
12. **Mode of study**	Full-time	Part-time
13. **Integration of work/study**	N/A	High
14. **Integration of practice/theory**	Low	High
15. **Cohorts**	No	Yes
16. **Variability of duration**	Very high	Low
17. **Research outcomes**	Long dissertation	Shorter dissertation, often more than one; project reports
18. **Assessment**	Dissertation driven	Separately assessed components
19. **Breadth**	Narrowly focused	More broadly focused, problem-driven

Given the findings of the graduate faculty's review of the literature, survey feedback from professional master's degree alumni, and needs assessments, the team worked to create an applied research – use-inspired, technology-focused, professional doctorate. The program is designed to serve an experienced and mature clientele who will demonstrate their proficiency in use-inspired research with an applied dissertation.

1.1 Professional Doctorate Program Design.

The Polytechnic Institute graduate faculty team has formally proposed the creation of a Doctor of Technology graduate degree program to be delivered as a hybrid model from the Purdue University-West Lafayette campus to active/employed technology professionals. In this proposal, they [11] stated:

> This degree program will be distinctly different than the existing Ph.D. in the Polytechnic in multiple ways including the delivery mode, the target clientele, the focus of learning activities, and the research aims of the program. In addition to purposing the degree towards the development of technology and R&D competence needed by business, industry and government, our vision is to employ a hybrid delivery system involving predominantly distance learning education plus some campus-based experiences that make the achievement of a doctoral degree far more accessible to practicing professionals who would not pursue a doctorate or Ph.D. in a traditional campus setting due to their work and home responsibilities.
>
> …
>
> The proposed Doctor of Technology degree is a professional doctorate [12], i.e., a terminal degree, focusing on in-depth understanding of and capability with technology and the concomitantly necessary, innovation and leadership skills of middle and senior leaders in industry, business, and government as well as NGOs. As contrasted to the 'traditional' Doctor of Philosophy's intent to develop *professional researchers*, the professional doctorate is designed to develop *researching professionals in technology* primarily for environments other than the academy. (p.3)

In accordance with the aforementioned design considerations, students in the professional doctorate program will be required to demonstrate the following competencies to graduate:

- Envision, plan and conduct applied research and development activities;
- Identify, comprehend, analyze, evaluate and synthesize research and professional practice;
- Evaluate technologies and technology-related programs and leadership activities;
- Assess individual performance with, and understanding of, technology;
- Communicate effectively and employ constructive professional and interpersonal skills; and
- Function at a high level in one or more of the technology disciplines.

1.2 Target professionals

The Polytechnic envisions that the bulk of the students who will be choosing to pursue the proposed Doctor of Technology will be practitioners from the middle and upper ranks of business and industry, i.e., persons with a documented record of performance and considerable relevant experience. Typically, this is observable by an upwardly directed career trajectory of increasing responsibility. Because the Doctor of Technology focuses on advanced practice, such indicators have more utility for predicting success potential than do standardized examinations.

1.3 Learning experiences & knowledge base

The Doctor in Technology design incorporates best practice instructional and learning technologies to deepen and accelerate learning by employing andragogic approaches and tailoring of the learning experiences to aid aspirants in furthering their education. The outcome will be competencies that can be readily applied in business, industry, government and NGOs, as well as by entrepreneurs, to solve complex technology-related problems. The proposed curriculum systematically develops enhanced skills and understandings that enable professionals, already holding a Master's degree or equivalent, to apply their heightened technical and conceptual understandings of technology, research and development as they work to develop strategies to advance/enhance their enterprise. Consequently, the Doctor in Technology will accelerate and further the career of such individuals as they contribute to enterprise performance, efficiencies and sustainability through contemporary applied research-based techniques. All students will be required to complete a dissertation focusing on applied/use-inspired research of direct relevance to professional practice.

The program builds upon the particular strengths of Purdue University, and its Polytechnic Institute (the largest technology unit at a Research 1 institution in the nation), by leveraging the national recognition and well established capabilities from existing units including Aviation and Transportation Technology, Computer and Information Technology, Computer Graphics Technology, Construction Management Technology, Engineering Technology and Technology Leadership and Innovation. Given the importance of information to advances in technology, engineering and science the noted strength of Purdue's Potter Library is germane to this point also. Furthermore, other units across the Purdue University Campus also provide a rich environment for the proposed professional doctoral program by enabling supporting/cognate areas of study. These units include, but are not limited to, the Krannert School of Management, and the Colleges of Education, Engineering and Science. [11]

Pursuant to the plan of study, students are required to take:

- 21 credit hours[2] of core curriculum consisting of:
    - Technology and Society (3 credit hours)
    - History of Science and Technology (3 credit hours)
    - Philosophy of Technology (3 credit hours)
    - Technology Policy and Economics (3 credit hours)
    - The Design Process (3 credit hours)
    - Technology from a Global Perspective (3 credit hours)
    - Technology Clusters and Domains (3 credit hours)
- 15 credit hours for a dissertation is required for the Professional Doctor Technology degree. This will be an applied R&D project focused on a current problem of a company or industry and the results must be defended to the graduate committee.
- 24 credit hours of specialization in any of the technological fields offered by the Polytechnic Institute and by Purdue University. These specializations range from aviation technology, various computer technologies, electrical, mechanical and industrial technologies, as well as technological innovation and leadership.

1.4 Innovative learning and instructional methodologies

The Doctorate of Technology degree program is a predominately distance program with an on-campus weekend face-to-face element; in this sense, it is a distance-hybrid program. Over 50% of the program will be administered through distance modalities. In a typical weekend format, each three-credit hour course will meet for approximately 5-7 face-to-face class hours; three times per semester, for a total of 15-21 seat hours

[2] A credit hour is the equivalent of 15 person hours of class time plus the attendant amount of homework and independent study

in each semester. Given 15 seat hours per credit hour in a given semester (45 seat hours per 3-credit hour course), that directly implies a distance percentage of 53% to 66% of each course will be provided via distance delivery. This mode of delivery will enable the practitioners to continue to work at their current jobs while taking courses to expand their breadth and depth of knowledge for their specialty.

1.5 Culminating/Capstone research and development experience

All students will be required to complete a dissertation focusing on applied/use-inspired research of direct relevance to professional practice in any of the arenas of today's complex technology-based enterprises. Typically, such dissertations will advance a state of a technology or practice from one Technology Readiness Level to the next higher level. This dissertation must necessarily be defended before the candidate's graduate committee. Note that it is recommended that the graduate committee contain one member from industry with specific expertise relevant to the dissertation topic and not a direct superior in the candidate's employing organization.

2 IMPLEMENTATION PLAN

The team's implementation plan for the proposed doctorate is detailed in the following bulleted steps. The initial steps involve securing the necessary approvals to offer such a degree and then the subsequent ones involve a sequenced process of piloting, revision and enhancement pursuant to continuous improvement and quality control principles.

1. Secure Institutional approval
2. Secure state government approval
3. Announce availability to potential ProSTAR[3] clients & recruit first cohort
4. Conduct doctoral faculty and major professor focus sessions
5. Deploy degree planning materials to enrolled cohort
6. Conduct induction training of first cohort students
7. Deliver semester one courses
8. Debrief cohort and faculty members
9. Revise and/or update semester 2 experiences
10. Schedule value-adding experiences
11. Conduct semesters three and four

3 CONCLUSIONS AND NEXT STEPS

Based on the reviewed literature as presented in this paper's Introduction, the authors concluded, as did the cited colleagues around the world, that a need for a professional doctorate did exist. Furthermore, it was also concluded, based on alumni and potential student surveys, that sufficient interest was manifested to make such a program viable. Pursuant to these two conclusions the author team evolved the program design presented in section 1 and then outlined the implementation steps in section 2. These steps are now underway and approval is being secured as per the outlined sequence.

ABSTRACT

The paper presents the main objectives and intended outcomes of a Erasmus + Project *Towards Excellence in Engineering Curricula for Dual Education* (TEEDE) coordinated by the University Rovira i Virgili (URV, Spain). The project has received funding under the Key Action 2: Capacity building in the field of higher education. This joint multi-country project including partners from Europe, Russia, China, India and Cambodia aims to promote the modernization, to expand the availability and to develop the internationalization of higher education in the partner countries: to promote intercultural and interpersonal exchange, and to promote the voluntary convergence with the tendencies of the development of higher education in the EU.

The main output of the project will be upgraded/developed curricula in engineering trades. It will be possible through development of methodological guidelines on professions and qualifications based on the analysis of the economic needs of the different regions involved.

Conference Key Areas: University-Business cooperation, Curriculum Development

Keywords: dual education, engineering education, curriculum development, university - industry cooperation

INTRODUCTION

Today many countries all over the world are seeking ways to strengthen the linkages among employers, workers, higher education institutions, and governments. One of the possible ways to meet this challenge is dual education. In this system, training for industrial trades is a shared responsibility of firms and schools. Trainees divide their time roughly equally between classroom and on-the-job training, with both pathways developed in paralel. As trainees, they (might) receive a lower wage than regular workers, but are guaranteed secure, well-paid jobs at the firm upon successful completion of the program and receiving of a certificate [1].

1 WHAT IS DUAL EDUCATION

Even a preliminary literature review [2,3,4] reveals a lot of distinctive features how dual education is understood and implemented in different countries. The variation in the details is not relevant for the purpose of this paper, as we will refer to the context of the TEEDE project [5], which determines the most important characteristics of the dual system as the following:

- Combines apprenticeships in a company and formal education in the same course.
- Students are workers of the company.
- Students have some sort of labor contract.

This means that perform an internship or develop the final year project in a company is not considered as a dual education, as the involvement of the companies are more superficial

Crucial to the system's effectiveness is the close collaboration of industry and higher education institutions. If we manage to establish/reinforce this kind of cooperation, then it will provide important advantages for all stakeholders:

- Labor contract.
- Development of apprentices under real conditions.
- Apprentices benefits also from coworkers knowledge.
- Hard and soft skills are simultaneously developed in the company environment.
- Facilitates school-to-work transition.
- Improved retention for employer.

The limitations for succesful implemetation of such a system could be:

- Training is more expensive than the school-based approach.
- Companies have to follow many regulations
- Companies are often specialized and unable to train apprentices in all areas and with the broad view of a master (*e.g.*, small and medium enterprises).
- More student effort required, as they have to combine both tasks.
- Organizational changes are required also for Universities, which are not characterized by fast response times and actions.

In order to share best European practices and to make dual system more widespread in engineering education in such regions as Asia and Russia the Erasmus + project *Towards Excellence in Engineering Curricula for Dual Education (TEEDE)* has started in October 2016 [5]. The project has received funding under the Key Action 2: Capacity building in the field of higher education. This joint multi-country project including partners from Europe, Russia, China, India and Cambodia aims to:

- Promote the modernization
- Expand the availability and to develop the internationalization of higher education in the partner countries
- Promote intercultural and interpersonal exchange
- Foster the voluntary convergence with the tendencies of the development of higher education in the EU.

2 TEEDE PROJECT

2.1 Consortium

The TEEDE project consortium consists of:

- University Rovira i Virgili (Universitat Rovira i Virgili): URV, Spain. Project Coordinator.
- University of Tampere (Tampereen Yliopisto): UTA, Finland.
- Institute Technology and Education (Universitaet Bremen): ITB, Germany.
- University of Pavia (Universita Degli Studi di Pavia): UNIPV, Italy.
- Tomsk Polytechnic University: TPU, Russia.
- Far Eastern Federal University: FEFU, Russia.
- Katanov Khakass State University: KHSU, Russia.
- Omsk State University: OSIS, Russia.
- Jilin University: JLU, China.
- Shenyang Ligong University: SYLU, China.
- Institute de Technologie du Cambodge: ITC, Cambodia.
- Royal University of Agriculture: RUA, Cambodia.
- Indian Institute of Technology Madras: IITM, India.
- The Indian Institute of Technology Kanpur: IITK, India
- European Association for Quality Assurance in Higher Education: ENQA, Belgium.
- Association for Engineering Education of Russia: AEER, Russia.

All partners of the consortium have a strong focus on technology and engineering and serve as regional centres for implementation of national strategies for training professionals. The problem of training professionals for the real sector of economy has emerged due to immense development of high technologies, shortening the period from development to implementation, growing technological needs of the society. As a result there exist a need for new approaches to the development of curricula sensitive and flexible to demands of companies based on innovations. This challenge is common for all regions involved in implementation of the project: EU, Russia and Asia.

2.2 Objectives

To meet this challenge in the course of the project partners will:

1. Identify needs, select key professions and areas of training.
2. Develop and modernize curricula implementing the principles of the dual education under the guidance of European experts.
3. Launch new or upgraded curricula, combining periods of study with periods of

training at leading enterprises.
4. Create a system of continuous professional development.
5. Create communication and recourse centres at partner universities.

The specific objectives of the TEEDE project are the:

- Modernization and creation of the bachelor and master's degree programs in engineering based on the European principles of dual education;
- Development and implementation of the methodology of management of educational processes in universities following the dual education approach;
- Strengthening relations of universities with exterior economic and social environment, creation and development of variants of the cooperation of universities and enterprises, promotion of employment of graduates;
- Creation of communication and recourse centers for promotion of the projects results and further implementation of the project's outputs beyond the project cycle period;
- Establishment of the unified procedure of evaluation of qualification level achieved by the persons who are studying in engineering and the recognition of learning;
- Construction of the trajectory of lifelong learning for the engineers.

2.3 Outputs

The main output of the TEEDE project will be upgraded/developed curricula in engineering trades. It will be possible through development of methodological guidelines on professions and qualifications based on the analysis of the economic needs of three regions.

These outputs will be available to all stakeholders through the created communication and resource centres as well as the project website and through open communication of the partners that secures the reliability and high quality of the project outcomes.

3 ACKNOWLEDGMENTS

This project has been funded with support from the European Commission. Co-funded by the Erasmus+ Programme of the European Union (573896-EPP-1-2016-1-ESEPPKA2-CBHE-JP).
This publication reflects the views only of the authors, and the Commission cannot be held responsible for any use which may be made of the information contained therein.

ABSTRACT

Smart HEI-Business Collaboration for Skills and Competitiveness (HEIBus, www.heibus.eu) is an Erasmus + Knowledge Alliances 2 (KA2) project. Its duration is 36 months (1 January 2017 – 31 December 2019) and it aims to develop smart and innovative new methods for Higher Education Institution (HEI) - company cooperation. With a budget of about one million euros, the project brings together five universities and seven companies from five European countries with strong expertise and experience in different fields. JAMK University of Applied Sciences is the main partner of the project. Seventeen associated partners from six European countries follow the progress of the project, utilise the results and take part in some project activities.

In the HEIBus project, there are eight work packages, which are 1) Management, 2) Best practices of HEI-company cooperation, 3) Multidisciplinary student-level real-life problem solving, 4) Expert-level real-life problem solving, 5) Flexible student mentoring by companies, 6) Quality assurance, 7) Evaluation and 8) Dissemination & exploitation.

The HEIBus project focuses on strengthening the collaboration between HEIs and companies by creating new innovative cooperation models. These models facilitate the involvement of students and staff from HEIs in international Research & Development & Innovation (R&D&I) projects proposed by companies.

Conference Key Areas: University-Business cooperation, Attractiveness of Engineering Education, Engineering Education Research

Keywords: Collaboration, innovation, multidisciplinary, flexible mentoring

INTRODUCTION

Europe is trailing behind the USA, Japan and Canada with regard to building a smarter economy. Competitiveness and rising levels of productivity are a crucial force behind sustained levels of economic progress and the wellbeing of citizens. In short, Europe needs improvements. To tackle the problems Europe has launched the Europe 2020 strategy, with objectives on employment, innovation, education, social inclusion and climate/energy. The Europe 2020 strategy identifies actions to boost growth and jobs.

The schooling systems in Europe are on a very good level, but we still need to improve the velocity of innovation, productisation and commercialisation. At HEIs, both the students and university personnel are frequently handling innovations that could be the basis of improved business in small- and medium-sized companies (SMEs) or create new business possibilities for larger enterprises.

Economic success demands that the company is innovative, which in turn requires different kinds of multidisciplinary know-how. The purpose of the HEIBus project is to increase, improve, widen and deepen HEI-company cooperation at the student and expert levels, promoting entrepreneurial thinking and innovations. The earlier RePCI project (www.repci.eu, funded by the EU Lifelong Learning Programme and carried out in 2013-2015) led to a fruitful cooperation between HEIs and companies. The feedback of HEIs and companies showed a clear need for even deeper and wider cooperation, however, such as multidisciplinary study area cooperation and HEI-company expert-level cooperation.

HEIs have many challenges, such as meeting future needs and challenges set by working life and developing teaching methods which motivate students to learn and carry out their studies in time. The labour market is constantly evolving, with the necessary skills, competences and qualifications changing over time. Traditional education does not always answer the needs of the field, and new teaching and learning methods for new skills are needed. It is important that the needs of working life (companies) be matched with the education provided. This is an ongoing process and can only be reached with HEI-company cooperation.

One key factor for the success of the companies is competent and motivated personnel. One way to achieve this is through deeper integration of the company with the student groups throughout the studies, which provides the company with a good recruiting tool.

1 BACKGROUND AND BASIC INFORMATION OF THE HEIBUS PROJECT

1.1 Partners

The HEIBus project consists of five university and seven company partners from five different European countries (Finland, Germany, Hungary, Romania and Spain) taking part in the project as full partners:

- JAMK University of Applied Sciences (main partner, www.jamk.fi/en/) and ITAB Pikval Oy (www.pikval.fi/en/) from Finland

- Technical University of Cluj-Napoca (www.utcluj.ro/en/), SC PRO Tehnic (www.pro-tehnic.ro) and Automates ACM SRL (www.automatesacm.ro) from Romania
- University of Miskolc (www.uni-miskolc.hu/en/), Electrolux (www.electrolux.com) and Robert Bosch Power Tool (www.bosch-garden.com/gb/en) from Hungary
- University of Applied Sciences Esslingen (www.hs-esslingen.de/en/) and Stoebich (www.stoebich.com) from Germany
- University of Jaen (www.ujaen.es/serv/vicint/home/index) and Valeo Lighting Systems (www.valeo.com/en) from Spain.

The group of company partners consists of SMEs as well as some large companies. Three HEI partners are academic universities while two are universities of applied sciences. The partnership comprises a perfect variety of different types of organisations and professionals. This provides very interesting and fruitful cooperation with different perspectives on each aspect of the project. There are also 17 associated partners (companies and organisations) from six European countries who follow the progress, utilise the results and take part in at least some of the project activities.

The project focuses on strengthening the collaboration between HEIs and companies by creating new innovative cooperation models. These models facilitate the involvement of students and staff from HEIs in international Research & Development & Innovation (R&D&I) projects proposed by companies.

1.2 HEI-company cooperation

Currently, HEIs and companies around the world are experiencing a renewed interest in strengthening their forms of cooperation. It has been proved that bridging the gap between HEIs and companies benefits both parties. Cooperation between HEIs and companies is not a new concept. There are cooperation programmes, which date back to the first decade of the 20th century [1] or are well-known internationally that have served as a reference model [2]. However, the idea of integrating working life with the learning process has its detractors. They place strong emphasis on exploitative internships and non-enriching jobs in which students are just observing instead of being engaged in productive work. To tackle this problem, there are associations such as the Canadian Association for Co-operative Education (CAFCE) [3], the Cooperative Education & Internship Association (CEIA) [4] and the German Central Evaluation and Accreditation Agency (ZEvA) [5] that guarantee the quality of cooperation agreements.

The mechanisms offered by HEIs to provide students with the opportunity to gain work experience, in their career fields, are included in the generic concept of Work Integrated Learning (WIL) [6]. According to the definition adopted by the Higher Education Quality Council of Ontario [7], work-integrated learning is the process through which students come to learn from experiences in educational and practice settings. It includes the kinds of curriculum and pedagogic practices that can assist, provide, and effectively integrate learning experiences in both settings. Depending on the context, the term WIL is often used interchangeably with other, similar terms such as “work-based learning,” “practice-based learning,” “work-related learning,” “vocational learning,” “experiential learning,” “co-operative education,” “clinical education,” “internship,” “practicum,” and “field education” [8]. However, many of these terms are also used to describe specific types of work-integrated learning. The most widespread types of WIL are:

- Cooperative education
- Internship

- Apprenticeship
- Field experience
- Mandatory professional practice
- Applied research learning
- Service learning

1.3 Work packages

The HEIBus project consists of eight work packages which are Management (WP1), Best practices of HEI-company cooperation (WP2), Multidisciplinary student level real life problem solving (WP3), Expert level real life problem solving (WP4), Flexible student mentoring by companies (WP5), Quality assurance (WP6), Evaluation (WP7) and Dissemination & exploitation (WP8). Four of them (WP2, WP3, WP4 and WP5) are implementation work packages which will be explained deeper in the following chapters.

The project addresses the flagship initiatives of innovation union, youth on the move and an agenda for new skills and jobs. The HEIBus project carries out several tasks where students, HEI experts and company experts are involved in solving real-life problems of companies. This boosts the new innovative ideas that can be quickly taken into use in companies.

2 BEST PRACTICES OF HEI-COMPANY COOPERATION

The aim of the Best practices of HEI-company cooperation work package (WP2) is to analyse the existing cooperation models providing real-life experiences between HEIs and companies in the following way:

- to analyse the state-of-the-art HEI student-company cooperation models
- to analyse the state-of-the-art HEI expert-company cooperation models
- to analyse different platforms and forums used in HEI-company communication
- to analyse the best practices on company involvement in HEI education

Descriptions of existing cooperation models and the main tasks are in *Table 1*.

Table 1. Existing cooperation models and the main tasks of work package 2

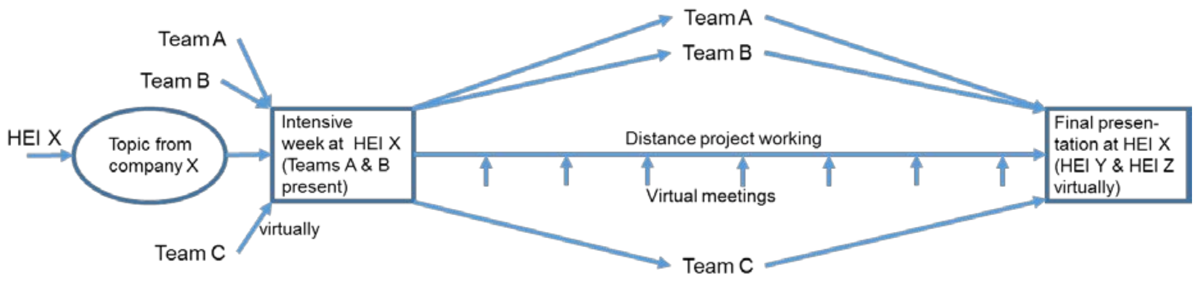
Student-company cooperation models	**HEI expert-company cooperation models**	**Internet based platforms for HEI-company communication**	**Company involvement in HEI education models**	**Coaching for virtual activities**
To search different existing methods or models	To search existing models	To find and analyse 15 internet based platforms	To search different existing methods or models	To ensure effective participation of all partners in virtual activities
To find at least 10 good and beneficial models	To find at least 10 good and beneficial models	To search best practices for communication	To search different levels of involvement	To organizes coaching of virtual methods
To select 5 models for deeper analysis	To select 5 models for deeper analysis	To build a new platform or to join in best available platform	To analyse different levels of involvement	To use social media for different project activities
To form background for the Multidisciplinary student level real life problem solving (WP3)	To form background for the Expert level real life problem solving (WP4)	To help continuation of the HEIBus activities after the project	To form background for the Flexible student mentoring by companies (WP5)	To invite associated partners to take part in virtual coaching

So far, all work package leaders have searched existing methods and models for HEI-company cooperation, which the leader of WP2 has collected. During April - May 2017 the best models for deeper analysis were selected. Regarding the outcomes of this work package, the best and most comprehensive ideas and models for HEI-company cooperation are expected to be found. These models will form a good background for the other implementation work packages, WP3-WP5.

3 MULTIDISCIPLINARY STUDENT LEVEL REAL LIFE PROBLEM SOLVING

The aim of the Multidisciplinary student-level real-life problem solving (RLPS, WP3) work package is to create a new model on how to spread the real-life problem solving method to a new multidisciplinary cooperation level. The aim of the work package is also to build a virtual implementation of the RLPS method. This frees the RLPS method from the confines of space and make it more accessible to students unable to travel, among others. It also makes the method easy to use anywhere in the Europe. RLPS focuses on bringing students, HEI staff and companies together. The idea is that students from different study programs and nationalities form mixed groups in order to solve a real-life problem that has been given to them by a company, as shown in *Fig. 1.*

In every pilot projects, three multidisciplinary and international student groups work upon and solve the proposed topic during one academic semester and compete with each other.



Team A: 2 students from HEI X + 2 from HEI Y and 2 from HEI Z
Team B: 2 students from HEI X + 2 from HEI Y and 2 from HEI Z
Team C: 2 students from HEI X + 2 from HEI Y and 2 from HEI Z

Fig. 1. Pilot Projects of WP3

At the end of the semester, the company tutors select a winning solution and HEI supervisors give grades.

Three first-round projects will be carried out in autumn 2017. In spring 2017 partner HEIs have had meetings with partner companies, discovered applicable and good topics and required tailored lectures for these implementations, created their own information material and have possibly held information sessions for suitable student groups, as well as announced an application period for students. The companies who will offer the topics for the first-round projects are ITAB Pikval Oy from Finland, Andaltec (www.andaltec.org/en/) from Spain and Automates ACM SRL from Romania. In May 2017, supervisors of HEIs chose the students for these three pilot projects. Finnish, German and Spanish students and supervisors will take part in ITAB Pikval project, Finnish, Hungarian and Spanish in Andaltec project and German, Hungarian and Romanian in Automates project. In the beginning of the implementations, two student groups will have one intensive week in the home country of the company giving the topic and the third student group will take part virtually in this intensive week. After the intensive week, all students will work at their own HEIs and members of a certain student group will cooperate virtually until the end of the implementation. After the first-round pilot projects, feedback from students, HEI supervisor and company tutors will be collected and possible improvement will be conducted before the second-round pilot projects. Three second-round pilot projects will be carried out in autumn 2018. This work package is expected to produce motivated students with good teamwork, project management, cultural and language skills.

4 EXPERT LEVEL REAL LIFE PROBLEM SOLVING

The Expert-level real-life problem solving (EXPERT, WP4) work package aims to develop and pilot a new cooperation model between HEIs and companies. This enables companies to bring more complex problems to be solved by international and multidisciplinary experts. This promotes innovation and knowledge transfer between HEIs and companies as well as increases the skills of HEI experts and the working life relevance of education.

In the beginning, a step-by-step process model is built and pilot projects for testing the model are planned, as shown in *Fig. 2.* In order to search for companies and their topics for pilot projects, an information sheet about expert-level real-life problem solving is created. Each HEI involved in WP4 makes a list of companies in their own country to be contacted (including partner companies and possibly other companies), sends them the information sheet and asks potential project topics. The topics are listed and each involved HEI selects two topics for the pilot projects from a list of the topics. The selection criteria are practical: when does the project need to have results, are suitable experts available for the project, etc.

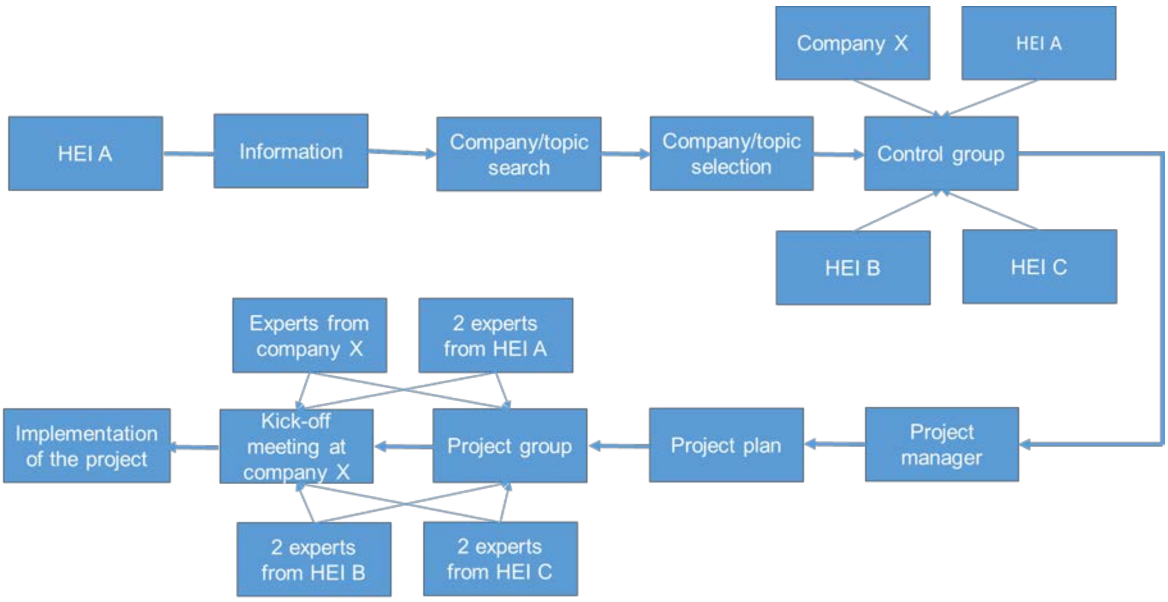


Fig. 2. Pilot Projects of WP4

There will be a total of six pilot projects where companies introduce a real-life problem to be solved by a team of experts from HEIs and companies. In order to make improvements and test the method, the six pilot projects will run in two phases. A control group consisting of representatives from each involved HEI and the company of the topic will be formed for each pilot project. The control group selects a project manager who is responsible for following the implementation, reporting the progress to the control group and running the practical issues of the implementation.

The project manager also makes the project plan, which is then accepted by the control group. The schedule of each pilot project depends on the needs of the company and the problem to be solved. The project manager supported by the control group finds and selects best experts for the problem to be solved and these experts form the project team. One team includes a total of six experts from three different HEIs (three different countries) and two experts from the company whose problem the team is solving.

The project is led by the project manager and implemented by the project team according to the project plan. In the beginning of each project, a kick-off meeting in the company is arranged where the whole project team is present. Other project meetings and the final meeting at the end of the project are arranged by video conferences (virtually). The project team agrees on the best ways of working together including virtual meetings, individual work, forming smaller teams inside the project team etc. The project team works on solving the real-life problem of the company and proposes a solution. With the help of the project team, the project manager reports the results of the project to the company.

After the pilot projects are implemented, feedback is gathered and analysed. In addition, an action plan for widening the international expert cooperation model outside the partner group is made.

The Expert-level real-life problem solving work package includes also building a virtual Expert Support Service with easy and quick access for all companies looking for expert services by HEIs. The Expert Support Service offers direct expert contacts for starting an expert-level RLPS, and a possibility to ask quick support for smaller problems.

5 FLEXIBLE STUDENT MENTORING BY COMPANIES

The Flexible student mentoring by companies (Flex Mentoring, WP5) cooperation model aims to find and test flexible ways to involve companies in the education process of students. Flexibility comes from different levels of involvement. Virtual reality, which is not dependent on time or place, is present in many activities, such as expert lectures and info sessions for a wider audience that makes it possible for students from international HEI partners, among others, to join by video conference, etc. The cooperation model also seeks to find out if Flex Mentoring could be a feasible solution for improving students' employment rate after graduation and helping students lacking behind in their studies or at risk of dropping out completely.

During implementation, one or more companies walk hand-in-hand with one study group from the beginning until the end of the studies. Each HEI partner selects two suitable student groups: one group consisting of students at the beginning of their studies and another group in which the students are at a more advanced level. Each HEI and company chooses the involvement level and methods best suited to them, in a flexible way. HEI teachers inform the student groups about the Flex Mentoring programme.

This work package contains the following tasks:

- to make plans on how the Flex Mentoring programme is implemented

- to select the most suitable involvement methods and to make detailed plans for the execution for each study year
- to review the plans after every study year and to modify if needed
- to create info materials of Flex Mentoring
- to introduce the materials to selected companies and student groups in every partner country

The main outcomes of this work package will be:
- increase motivation and study success for students
- easy recruitment way and a good labour force for companies
- good knowledge transfer between HEIs and companies

6 SUMMARY

The HEIBus project started in the beginning of 2017. So far, the biggest challenge has been getting all the needed documents from some company partners in time. Most of the activities have focused on WP2 because it forms the basis for other implementation work packages. Also in WP3 the planning of the first-round pilot projects is progressing well. In WP4 the process model has been created, and planning for the first-round pilot projects has started. In WP5 the plans on how the Flex Mentoring programme is implemented have done, the most suitable involvement methods have selected and the detailed plans for the execution for each study year have made.

Development of a series of design build projects
- Preparing students for industrial placement

G A Thomson
Aston University
Birmingham UK
E-mail: g.a.thomson@aston.ac.uk

ABSTRACT

Many modern engineering degree programmes make use of active learning often built around a variety of problem and project based learning activities. Structuring these to ensure a progression of both technical and professional competencies is key, with the emphasis often being focussed around the scientific and technical competencies to the detriment of the generic skills needed in industry.

This paper describes the creation and evolution of a series of major group projects over the first two years of Bachelors level degrees in Mechanical Engineering & Product Design aimed at developing students to a point where they are both confident enough and competent enough to undertake a year in industry at the end of their second year.

Mapping both the technical and personal qualities of a successful placement student and the typical entry competencies of our students, a series of requirements were developed and these structured into a coherent programme of project modules spanning two years.

Conference Key Areas: Curriculum Development, University-Business cooperation

Engineering Skills

Keywords: Industrial Placement, Skills, Employability, Project Based Learning

INTRODUCTION

To provide the best for engineering students, educators work hard to provide engaging and relevant programmes which are valued by both the students and the industries into which they will be recruited.

An increasingly common focus is the need for "employability" to try to ensure graduates emerge into the workplace with a holistic set of both technical and non-technical skills necessary to succeed and be readily useful to their employer. The use of industrial placements with students working in industry for a period of typically up to a year at some point during their degree is seen as a key part of this employability strategy for many but it itself requires students to be adequately equipped to successfully take on these positions in industry.

1 CONTEXT

1.1 Engineering Curriculum Design

In spite of Universities often emphasising research to inform staff recruitment and other strategic decisions, increased competition for students, availability of programme quality information to potential students and governmental pressures have seen much more emphasis placed on the quality of teaching provision.

This has seen Universities rethink their curriculums to best achieve the desired outcomes. [1]

In particular while discrete under-pinning scientific knowledge remains core, a greater emphasis has often been placed on holistic curriculums which integrate technical knowledge with broader personal, organisational, problem solving, commercial and team skills. This is exemplified by initiatives such as “CDIO” which aim to provide broad based programmes delivering high levels of employability. [2]

1.2 Employability

Employability is a key driver in the provision of the majority of engineering degree programmes. This is not unsurprising in a vocational subject with graduates enrolling in degrees to allow them to be equipped with the necessary skills, knowledge and personal qualities required for a career within the discipline. In addition, employability metrics – eg. proportion of graduates in graduate level posts – are commonly used in programme and institution league tables and rankings.[3]

Achieving employability within engineering programmes involves creating a curriculum which covers not only the technical skills required of engineers but also builds the students’ confidence, people, team, commercial and other skills with these non-technical skills often to be found lacking particularly among engineering students. [4-9]

For engineering students, learning is typically developed through a blend of conventional lectures, tutorials, formal laboratory exercises and projects. While lectures may be seen as a resource effective way of transferring underpinning engineering knowledge, they often lack context and this can be particularly the case for the personal, social and professional skills needed of the employable graduate and as a result a more experiential project based learning approach can be seen as more desirable.

1.3 Industrial Placement

For students at many Universities in the UK and elsewhere there is an opportunity to take part in a short or long term industrial placement as part of their degree. This is designed to allow students to not only contextualise the knowledge and skills being developed at University but also to expose them to the workplace, its approaches, conditions and cultures and in so doing develop their employability ahead of returning to their studies and graduation. Placements are typically taken after two years of study. For satisfactory placement experiences for both the student and the employer it is therefore important that adequate skills, both technical and non-technical are built up ahead of the student undertaking the placement.

2 PROJECT BASED LEARNING

2.1 Focus

To try to develop a broad based engineering education, significant emphasis has been placed on project and problem based learning. See eg. [10-12]

Aston University in Birmingham, UK runs mechanical engineering and product design degrees following a CDIO approach. As with all degrees at Aston, they offer students the opportunity to undertake year long industrial placements between years 2 and 3.

Prior to adopting the CDIO approach the degrees at Aston were very traditional, with large numbers of discrete modules, generally focussed around core engineering science disciplines with little integration between modules or attention given to non-technical skills. Under the adoption of the CDIO principles a project based focus was evolved and a plan was developed to determine the contents of these to ensure students would grow as individuals, while also developing the necessary technical and non-technical skills and knowledge to enable them to undertake a successful placement.

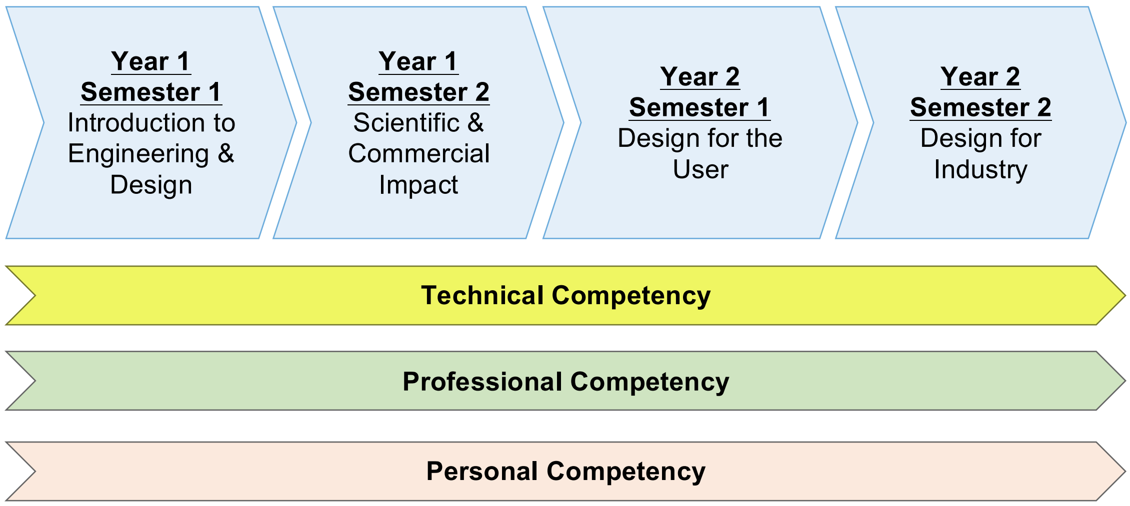

Fig 1. Student journey through year and two projects

It was decided that the first two years of the programme would therefore feature four major project elements accounting for half the students' time and credits, the balance being more traditionally taught engineering science and mathematics classes. These projects would then hopefully impart many of the employability skills necessary for successful placement. *Fig. 1* shows a top level approach to the resulting project curriculum with a theme identified for each project.

3 PROGRAMME DEVELOPMENT

3.1 Curriculum requirements

From reviewing research in the area and working with our own industrial board it became apparent that our previous programmes offered little opportunity for students to develop or practice their non-technical skills. These were entirely absent from the curriculum or existed in a theoretical and non-contextualised approach eg. a module in project management, taught purely by lecture and assessed by exam.

A range of technical and non-technical skills which might be required of a student entering an engineering placement were drawn up based on the literature, dialogue with industrialists, our own experiences and also the requirements of the relevant accrediting body. A list of some of these skills can be seen in table 1 with the intention that these could be developed through the project modules.

Table 1. List of Technical, Professional and Personal Competencies to be covered by project modules.

Technical Competency	Professional Competency	Personal Competency
Technical drawing	Commercial awareness	Self-reflection
Design methods	Engineering ethics	Self learning
Design for manufacture	Presentation skills	Time management
Analysis to support design	Project management	Leadership
Experimentation in design	Communication	Team membership
Critical review	Team working	Organisation
Component selection	Costing	Time keeping
Engineering standards	Meeting management	Accountability
Tolerancing	Documentation	Responsibility
Product specification	Legal responsibility	Confidence
Product requirements	Intellectual property	Empathy
Problem solving	Etc…	Etc…
Systems design	….	….
Etc…		
…		

3.2 Phasing

As with any educational approach it is important to introduce material to students at an appropriate phase in their development and also allow opportunities to reinforce, deepen and broaden the particularly key topics and where possible these link into non project areas of the curriculum.

In year 1 it was felt key that students focus on their technical and personal competency. Students were typically entering University directly from school and had come from a very heavily coached environment with often little consideration for the uncertainty and variability of real problems. They were also unfamiliar with group projects and working with others in a meaningful way. Professional competency was phased in more heavily at a later stage as students developed through year 2 and approached their placement at the end of the year.

3.3 Mapping

Table 2 shows the mapping of some of the key competencies with the student journey toward placement.

Table 2 : Mapping of core technical, professional and commercial competencies against the project modules.

4 REVIEW AND CONCLUSIONS

The programme is now at a stage of maturity with a number of cohorts having emerged from these projects and progressed into industrial placements and beyond into the workplace. Feedback from students emerging from placements is that these modules are key in helping them once in placements and while they can only partly provide some of the culture and learning they will experience once in work, certainly smooth the pathway.

Moreover the modules are seen as important in helping secure the placement posts which are typically competitively recruited among under-graduates from a range of programmes and Universities. Students are encouraged to take along project log books or other materials from their projects to evidence their development to the potential employers and this has proved a key factor at converting interviews to offers.

A recent quote from a student is typical – "*at my interview I presented my log books which details all the projects I have taken part in from the CDIO modules at Aston. The company representative at the interview was very impressed with how the course focuses on projects and specifically mentioned that the skills I had gained as a result were well suited to the industry."*

The approach is not without issues. The mapping aligns the technical, professional and personal topics to modules based on a theoretical ideal but this may then conflict with the theme of the module not always being a perfect fit for all the outcomes. Alternatively there may be resource issues with staff or workshop availability needing to be synchronised carefully.

The operation of the modules and the preparation of students for industrial placement is however one of continuous improvement and the approach and detail within the projects is continually evolving.

Nonetheless our experience has shown that, well-structured holistic modules are a key asset in help students obtain and succeed within industrial placements.

ABSTRACT

We developed a project to achieve the realization of Industry 4.0 in objective identification and smart sense through network communication in an echo system of production lines. The machine vision was carried out with OpenCV and NI Vision. With robotic-assisted Uarm Metal, measurements of the specific physical properties for the identified objects were implemented with embedded microcontroller utilities. Finally, the test results were uploaded to the public cloud server, ThingSpeak. The connection on the practical mechanical system and the platform of information interaction demonstrated the paradigm of the cyber-physical system.

Conference Key Areas: Engineering Skills, Physics and Engineering Education

Keywords: objective identification, smart sense, internet of things, industry 4.0

INTRODUCTION

The fast development in network communication and cloud computing in the past decade has boosted the evolution of computer technology, programming design, and information management to a whole new stage of application and service, and has stimulated the dream of the realization of the Internet of things (IoT) [1]. Benefiting from the worldwide population of wireless remote control, sensing devices, and advanced measurement and display instruments, innovations in the IoT related technologies and market demand continue to expand and are setting the standards of future technology. Meanwhile, the integration of embedded systems and computer languages has turned the production and manufacture into new types with better efficiencies—smart sensing, together with custom manufacturing, have established the key feature of Industry 4.0 (I4) [2]. Furthermore, with the development of the cyber-physical system [3], the connection between virtual and real worlds has been established, bringing with it IoT environments with vivid objective communications, artificial intelligence, and human-computer interactions.

As the current industrial production still faces many critical challenges in smart automation because of the increasing complexity and the need for flexibility [4], the requirements that include portability, interoperability, and reliability have been identified as prerequisite for future industry. Among various strategies, machine vision provides innovative solutions to reduce difficulties in the direction of industrial automation [5]. A variety of applications of vision systems provide evidence of the practices and effects of optical inspection. In general, the processes of machine vision include image acquisition, image processing, feature extraction, and identification judgment. To achieve precise identification in complex or highly-sensitive environments, such as face recognition, a feature-based or figure-based algorithm would be considered. As a result, reliable identification depends not only on high-resolution image acquisition; the efficiency of the recognition software matters as well.

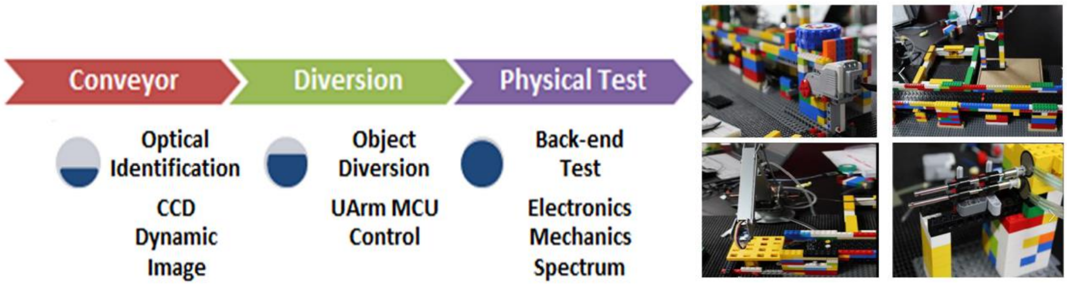

Figure 1. The flow of optical identification, object diversion, and back-end test. The production line and measurement platform are constructed from LEGO modules.

In this work, we report the development of a project in cooperation with Yulon Motor Group to achieve the realization of I4 in objective identification and smart sensing through network communication on an echo system of production lines. The project was implemented in the two-month summer vacation after a four-month lecture course that introduced the kernel, the aim, and the practice of I4. Before proceeding, students have to submit the proposal and the budget to demonstrate their idea, schedule and processes to design the project with the classroom equipment by applying the previously learned domain knowledge. In doing the project, students were guided to construct, review, and revise their blue chart. This greatly helped build a clear picture for what to do, how to do, and flow debug, and then greatly increase the probability for students without engineering background to complete the project of image identification in time.

In terms of the software structures, the image identification was implemented parallel with two schemes, OpenCV (Open Source Computer Vision) and NI Vision (National Instrument Vision). OpenCV is open source software with powerful libraries for image processing, and supports C, C++, Python, and JAVA. In contrast, based on the graphic-based interface, LabVIEW, NI Vision was designed as commericial software. In this work, we designed programs for dynamic image acquisition, identification and analysis with Python and LabVIEW, and compared the identification results and specific advantages of the two algorithms.

In terms of the hardware structures, we constructed and controlled the conveyor and mechanical system with LEGO EV3 and servo motors. After image identification, the object diversion to the back-end physical-test platform was performed with robotic-assisted Uarm Metal. The utilization of the ATmega168 chip and Arduino IDE (Integrated Development Environment) helped easily realize the simultaneous control of three-axial motors and Bluetooth sensors, and completed the diversion. In this project, we further designed a measurement platform for three physical properties including notch depth, battery capacity, and strain. The control of the mechanical system of the platform was achieved with Arduino Uno combining pressure and voltage sensors. The measurement of the strain in terms of optical pulse deviation from fiber gratings provides an alternative for fragmental detection. Finally, the test results were uploaded to the public cloud server, ThingSpeak, via the ESP-8266 Wi-Fi module to supply the service for information interaction and feedback.

EXPERIMENTAL SETUP

Based on the LEGO EV3 dynamic modules, we developed a project of objective identification and established a physical-test platform on an industrial production line to simulate the object diversion and quality management in the smart manufacturing. The experimental setup is demonstrated in Fig.1.

EXPERIMENTAL METHOD

With a CCD/webcam to capture the image of objects (tires, batteries, and engine gaskets) that are carried randomly on the conveyor belt dynamically controlled by servo motors (Fig.1 right & Fig. 2a), we use two computer vision software packages (OpenCV and NI Vision) for the recognition of object characteristics. The item information of passed objects is transmitted to the robotic arm, Uarm Metal, by the bluetooth module, while the defective objects are disposed of in the recycling area. The three-axis motor and electromagnet are controlled via the ATmega chipset in the Uarm, by which the objects will be suspended and carried to the correct backend platform for property characterization, including tread depth, battery power, temperature, and pressure. We use Arduino and different sensors for measurement, and the test results are uploaded to the cloud server, ThingSpeak (Fig. 2b) by Wi-Fi. This web page is a public platform, where both the engineers and customers can freely check the dynamic production line process, and send their opinions back via the embedded Google form. The complete experimental procedure is depicted in the flow chart below (Fig. 3).

RECOGNITION THEORY

[1] OpenCV—Python

The OpenCV supplied machine vision is completed via (i) background photo shooting with the webcam or CCD, (ii) grey-scale transformation, (iii) dynamic image acquisition and background extraction, (iv) threshold setting and noise filtering, (v) configuration positioning, and (vi) Matchtemplate supplied database comparison.

In the edge control and threshold setting, the Canny Edge Method [6] also known as the optimal detector, is adopted. With the Canny algorithm, the image recognition through Gaussian filtering, Sobel test, non-maximum suppression, and two-threshold hysteresis would be expected to satisfy a low error rate, good localization, and minimal response.

Template Matching is a method for searching and positioning of a template image in a larger image. In the convolution process, the template image slides over the input image and compares the template and patch of input image under the template image. By using TM_CCOEFF, it returns a greyscale image of global maximum (R) according to

$$R(x,y) = \sum_{x',y'} (T'(x',y') \cdot I'(x+x',y+y')), \tag{1}$$

where

$$T'(x',y') = T(x',y') - 1/(w \cdot h) \cdot \sum_{x'',y''} T(x'',y''), \tag{2}$$

$$I'(x+x',y+y') = I(x+x',y+y') - 1/\,(w \cdot h) \cdot \sum_{x'',y''} I(x+x'',y+y''), \tag{3}$$

record the correlation of the neighbourhood of the pixel between the template T in the size of $w \cdot h$ and the object image I.

[2] NI Vision—LabVIEW

The NI Vision supplied machine vision is completed via (i) localhost setting and dynamic vision acquisition, (ii) threshold setting, (iii) look-up table generating, (iv) grey morphology, and (v) OCR/OVR conversion.

After image acquisition, we set the threshold for color-grey conversion and set the pixel number in the grey scales by means of bilevel thresholding. To enhance the contrast and the lightness of the image, we then generate a look-up table to renew the grey scales. Further, we apply Greyscale Morphology to trim the configuration of the object in terms of masks of erosion, dilation, opening, and closing [7]. Finally, we apply OCR (Optical Character Recognition) and OCV (Optical Character Verification) to work out analog-digital conversion for computer recognition. The identification program in the LabVIEW structure is shown in Fig. 4.

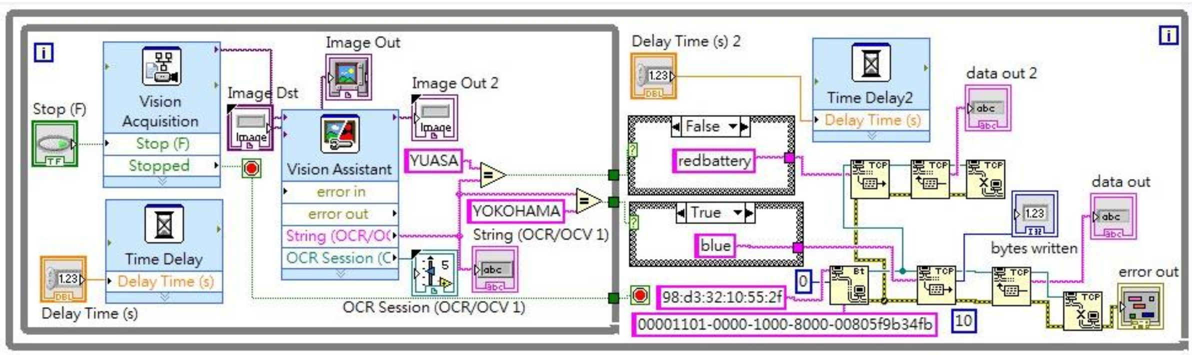

Figure 4. Implementation of objective identification by graphic-based interface of LabVIEW.

RESULTS

Fig. 5 and 6 display the flow charts of objective identification with text-based OpenCV and graphic-based NI Vision, respectively. In both schemes, the recognition proceeds following the rule: image acquisition, image processing for background extraction, grey-scale modulation for noise elimination and contrast enhancement, and finally database comparison. Essentially, the threshold setting is critical in the determination of the limitation and efficacy of grey-scale modulation to shape and configure the image. For database comparison, we adopt surface inspection to implement the characteristic identification. To avoid reflection smear, a strong color contrast is suggested to clearly distinguish between the characteristic symbol and the image body.

In this project, the recognition is precisely achieved in both schemes. However, compared with the commercial suite, it is truly a challenge for the beginners to understand the recognition theory and build the programs with the open source. But on the other hand, the use of OpenCV takes the advantages to easily connect with the embedded system while the realization of remote control via LabVIEW-for-Arduino becomes a new task, too.

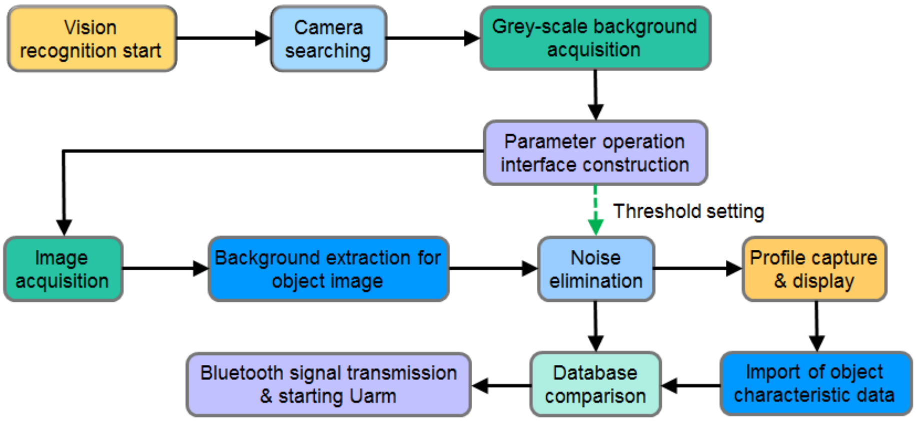

Figure 5. The flow chart of objective identification with OpenCV.

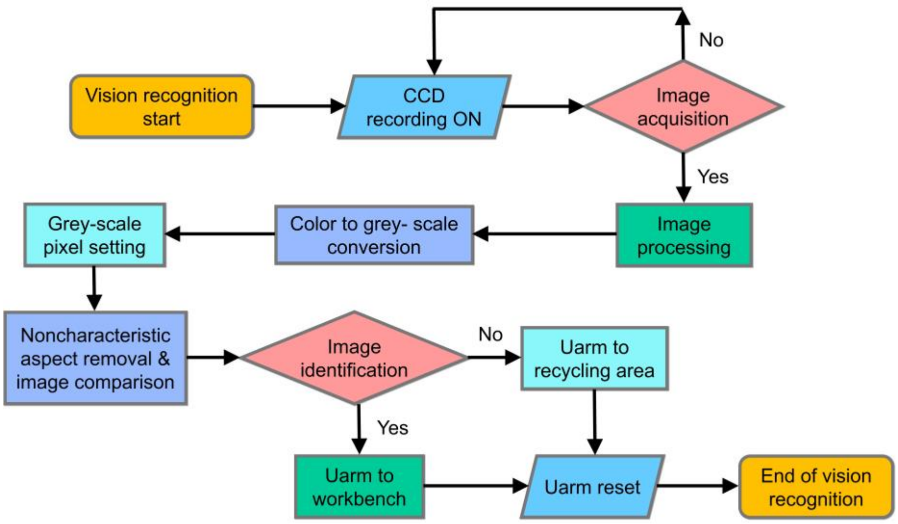

Figure 6. The flow chart of objective identification with NI Vision.

Fig. 7 left demonstrates the grey-scale images of the objects and characteristic surfaces that serve as templates of the database. The image identification is to calculate the correlation between adjacent pixels of the template and the object via the convolution process. As blue lines depict uncorrelated patterns, the red lines denote well-matched patterns that are delivered to physical tests (solid) or to recycling area as defects. The graphic interpretation of the digital image convolution is shown at the right-hand side of the figure.

After image identification, the object diversion to the back-end physical-test platform for notch depth, battery capacity, and strain measurements is carried out with robotic-assisted Uarm Metal. The utilization of the ATmega168 chip and Arduino

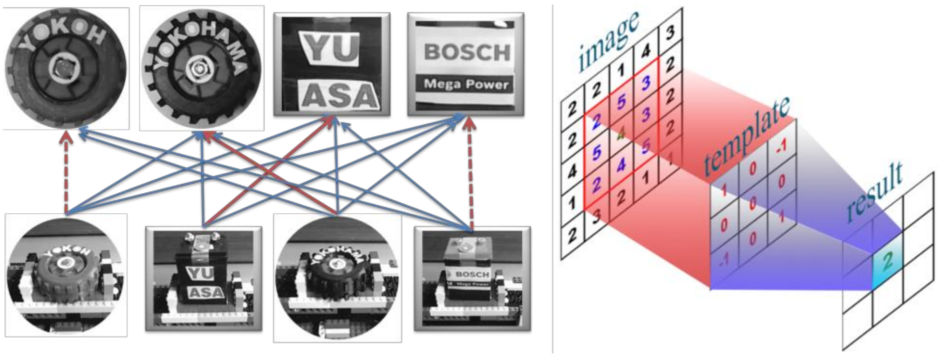

Figure 7. Grey-scale images and graphic interpretations of image convolution of characteristic templates and objects.

IDE help realize the simultaneous control of three-axial motors in the Uarm and Bluetooth receiver and transmitter, and complete the diversion.

The control of the mechanical system of the platform was achieved with Arduino Uno combining pressure and voltage sensors. The measurement of the temperature- and tension-induced strains in terms of optical pulse deviation from fiber Bragg gratings provide an alternative for fragmental detection. In Fig.8 we show the variation of strain intensity with wavelength measured by the high performance optical spectrum analyzer, Agilent 86146B.

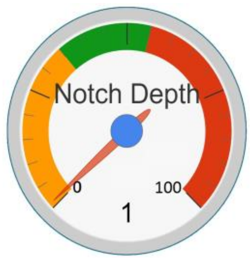

Figure 9. The notch depth meter on ThingSpeak.

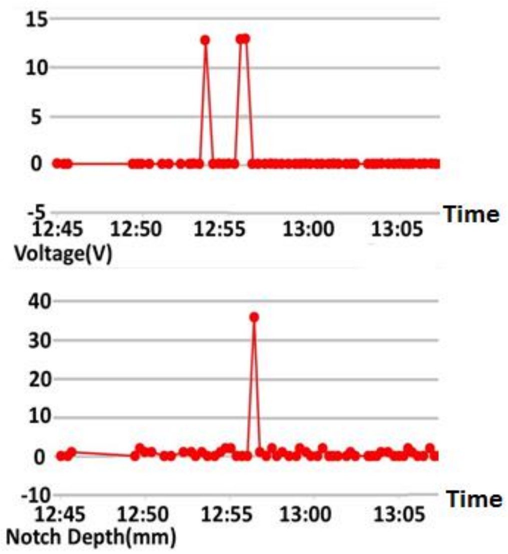

Figure 10. The dynamic records of voltage and notch depth on ThingSpeak.

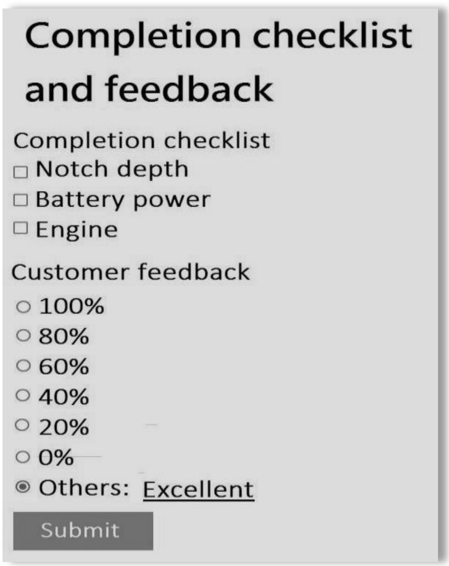

Figure 11. The completion checklist and real-time customer feedback.

Finally, the test results in terms of notch depth meter (Fig. 9) and dynamic records (Fig. 10) were uploaded to the public cloud server, ThingSpeak, via the ESP-8266 Wi-Fi module to supply the service for information interaction and real-time customer feedback within the Google form (Fig. 11).

SUMMARY

Via the integration of embedded microcontroller utilities and physical sensing environments, this project successfully demonstrates in the laboratory the kernel of Industry 4.0 in customized smart detection and the Internet of things through front-end objective identification, back-end physical properties measurement, and a cloud-supplied information platform and stimulate interdisciplinary collaboration between science and engineering for physics undergraduates.

From the perspective of engineering technique, the connection of the practical mechanical system and the platform of information interaction demonstrate the paradigm of a cyber-physical system. From the perspective of engineering education, the project-oriented training provides the opportunity for students to experience the practical operation, difficulties, and the need in maintaining a factory. Therefore, this provides the opportunity for students of science and engineering to work together and to stimulate new ideas and imagination to propose feasible solutions and suggestions to help improve the reliability and efficiency of the production and the manufacture. By means of the image identification, physical tests, and cloud interactions, our project has successfully demonstrated the idea and operating processes to approach the dream of smart factory.

Engineering Skills

Enhancing Employability through Leadership Training

P. Willmot
National Teaching Fellow/Principal Teacher
Loughborough University
Loughborough, England
E-mail: P.Willmot@lboro.ac.uk

ABSTRACT

Most university engineering degrees include elements of teamwork experience to a greater or lesser extent and students are frequently placed in positions of leadership. Few universities, however, actively develop leadership skills or provide targeted training as a primary objective within course modules. Leadership coaching is a competence that is outside the experience of most engineering academics and providing it offers a new challenge for them. This paper compares two models for teaching 'leadership', offered as options in the final-year of an undergraduate engineering programme. Both use methods far removed from the usual diet of lectures and examinations. One is focused around a semester-long activity where senior students take responsibility for a team of younger students undertaking an industrially-based project. It is supported by a series of activity-based workshops. The second has similar objectives but is very different in style; it encapsulates a three-day intensive outdoor management course that exemplifies team-work and leadership theory through hands-on activities and provides the main focus for pre-course learning and post-course assignments. This paper describes the two variants and the philosophy that inspired them. A short survey reveals how a year-group of students responded to the different training methods and provides a comparison of the two educational models.

Conference Key Areas: Curriculum Development; Engineering Skills; Continuing Education and Lifelong learning.

Keywords: employability; skills; teamwork.

1 INTRODUCTION

When asked to describe what professional engineers do, most think strictly in terms of science and technology. They point to examples of familiar products and constructions such as cars, aeroplanes, computers, or bridges to describe outputs of the various engineering disciplines. Not surprising then, that if asked what students of engineering should be taught, we would naturally fall on the fundamental science that lies behind the understanding of these complex products together with the principles of design that brought them into being.

The most valuable asset of an engineering business however, is neither its steel stock nor its production machinery but the people it employs. Engineering is a team activity; possibly more of a team activity than any other business. Modern manufacturing depends on people with a diverse range of knowledge and skills who must work together to a common end. We, in the universities, are training tomorrow's employees of engineering business, so we should devote at least some of our available time on people skills if our graduates are to become effective members of the team right away.

Whilst 'hard' intellectual skills still dominate in academia, there appears to have been a transition in the workplace where skills which develop Emotional Intelligence (EI) are, apparently, just as important. It was recognised thirty years ago, that intrapersonal and interpersonal intelligences are just as important as the type of intelligence typically measured by IQ[1], and later studies declared them to be even more so. For example, Feist & Barron [2] wrote that social and emotional abilities were four times more important than IQ in determining professional success and prestige, while a recent UK survey further emphasised the importance of soft skills in respect of employability, personal development and career progression. It declared that hard skills help engineers qualify for a job or role, but soft skills dictate career growth and progression. [3] Highly developed EI is particularly important for tomorrow's leaders. The UK Institute of Leadership and Management quotes Daniel Goleman's work [4] in which he suggests that these skills contribute more than 85% of what enables star performers to become great leaders.

Goldberg [5] suggested that students currently spend 80% of their time studying technical subjects but these technical skills developed only constitute 20% of an individual's working day. So, not surprising that the recruitment of graduate engineers seems to focus more than ever on soft skill competencies.

In response, the ASEE [6] proclaimed that "engineering education programs must, not only teach the fundamentals of engineering theory, experimentation, and practice, but be relevant, attractive, and connected," preparing students for a broad range of careers and lifelong learning. And both ABET and the Engineering Council (EC), the bodies in the USA and UK respectively that define engineering accreditation routes list the required 'professional competences' including both 'hard' and 'soft' skills. Specifically, the EC now specifies generic competences for Chartered Engineers that include the ability to "Lead teams and develop staff" and to "Organise and lead work-teams" [7]. While most university degrees include elements of teamwork experience, few specifically address these leadership requirements or provide targeted training. Leadership training tends to be the preserve of professional development specialists and is outside the experience of most academics in engineering.

Despite this, and similar proclamations in other parts of the world, later studies highlight the perception from industry professionals of a soft skills gap within graduates and hold higher education institutions responsible. Meanwhile, employers are becoming more reluctant to invest in graduate training and development[8] due to the perception that this generation that are more likely than ever to leave the company after a short period. Kumar and Hsiao [9] summarised that *"Engineers learn soft skills the hard way"* supporting the theory that engineers enter the market place technically qualified but not sufficiently competent in soft skills.

A small number of curriculum designers in the UK have been inspired to respond, taking advantage of the additional teaching time available in our extended undergraduate Master of Engineering (M.Eng.) Degree. The integrated M.Eng degree was promoted and controlled by the Engineering Council in the late 1990s to be the premier fast-track route to senior professional registration for high achievers. These degrees were to have enhanced learning outcomes beyond those of the Bachelor degree in respect of both technical and transferable skills. With regard to leadership and teamwork skills, the question is; how should they be taught? If we are to prepare our most able students in the image proposed by our professional body, it is apparent that we will need to learn and adopt some pretty innovative methods.

2 UNDERGRADUATE LEADERSHIP MODULES

Two innovative 'leadership' modules have been introduced to the final year of a mechanical engineering M.Eng programme. The students choose which route they prefer. Both modules use methods of teaching and learning, far removed from the usual diet of lectures, tutorials and unseen examinations. The first is built around a semester-long 'mentoring' activity where senior students are given responsibility for a small team of year-2 students engaged in an industrially based project. The central activity is supported by a series of activity based training workshops that focus each week on a different 'people management' skill. The second module encompasses a 3-day intensive residential teambuilding and management development course that exemplifies a short preparatory course of management and leadership theory through hands-on exercises and challenging outdoor activities.

2.1 Module D500 'Project Leadership'.

All second-year students complete a mandatory team project which runs from October to February taking up one afternoon per week. Each team of four students is assigned to an industry-inspired project generated and supported by a group of companies known as the 'Loughborough Teaching Contract'. A final-year student studying project leadership is then attached to each project team, as mentor and this experience forms the central activity of the 'Project Leadership' module. Mentors are expected to chair weekly team meetings that last about 45 minutes and become involved in all aspects of the project at a supervisory level.

The mentor's primary role is that of project manager, who deals with project planning, gives advice and guidance, allocates duties to team members and encourages effective progress. Mentors assist with the promotion and development of ideas, and offer sound one-on-one advice on methodology, analysis and evaluation. They are, however, told to refrain from directly generating solutions or actually performing the technical tasks. Mentors quickly learn the effects of different leadership styles and the need to pay attention to human factors as well as to the technical tasks.

Academic supervisors observe meetings every two or three weeks and are therefore able to monitor the situation and intervene if all is not running smoothly however on many occasions the mentor is left to take charge. Supervisors complete an appraisal checklist and discuss it with the mentor after each observation to provide developmental feedback and support. Supervisors provide a safety net and are ultimately responsible for both the mentors and the student teams including the assessment of both. The objective, however, is for mentors to be given responsibility and therefore to experience first-hand leadership and in the majority of cases supervisors feel able to stand back.

While the mentoring activity is central to the module, to realise the maximum benefit they also need parallel coaching in aspects such as chairmanship, project planning, time management, human resource management, team dynamics, leadership styles and motivation theory. Most importantly, they need the opportunity and encouragement to reflect on events and what are the causes of subordinate reactions in the wider context. A programme of seminars provides a weekly forum in which the mentors are encouraged to discuss and share their experiences and to learn new techniques. The taught element is 'activity based' borrowing most materials from staff training and development organizations.

When this module was first introduced, there was a lecture programme, however it was clear that, although the students listened politely, they had little real interest in non-technical topics taught in this way and, as a consequence, failed to really develop professionally or properly understand the mechanisms of human interaction. Hence, the lecture programme was replaced by the more effective workshops.

2.2 Module D517 'Teamwork and Leadership'.

This option is built around an outsourced 3-day residential Outdoor Management Course (OMC) currently provided by the Lindley Educational Trust. The Trust undertakes development activities with people of all ages and is experienced in constructing themed development courses for groups ranging from primary school children to senior company executives. This particular course was developed jointly by the staff of the Trust and the module leader at university. University staff accompany the students throughout the course acting as observers. Some of the topics that are fully explored and exemplified through outdoor activities are: the behaviour of individuals and groups, balancing the needs of the task, the team and the individual, leadership styles and skills, motivation and working under pressure.

In the weeks running up to the outdoor course, students attend just 3 seminars 'teamwork' leadership style' and 'motivation' and research appropriate theory such as John Adair's work on leadership and leadership styles, Tannenbaum and Schmidt's style continuum and Belbin's team roles. They research and present a case study as an oral report accompanied by a short written document. At this point, we believe that, although the students perform this task well, they are fundamentally unconvinced of the purpose or usefulness of such theory, nevertheless it provides a good foundation and all becomes much clearer during the reviews and feedback sessions that form an essential part of the residential course.

The course takes place in 'the Hollowford Centre: a purpose built training centre in the heart of the Peak District National Park in central England. This is a sparsely populated craggy mountainous region noted for outdoor leisure activities such as rock climbing, caving and hill walking. It is through this type of activity amongst others that we enthuse the students and empower them to develop their individual strengths, create positive relationships and construct effective work cultures. This type of course is popular with many commercial organisations for teambuilding and management development but rarely available as part of the engineering curriculum in British universities.

Fig. 1. Students tackling various indoor and outdoor challenges.

The intense activities are led by experienced professional trainers and begin with short ice-breakers, problem solving activities, and a raft building exercise. Teams are formed and each team earns virtual money through successfully completing exercises and the money is carried over to the next task. Each activity is designed to bring out a different aspect and the students are expected to take on different team roles. They all experience leadership in some form by the end of the course. Half way through day 2 a major 24-hour exercise begins. This runs late into the night with the teams only returning to the centre for a short sleep and then carries on into day 3. The exercise simulates a manufacturing construction business scenario; assembling a product, via the purchase of materials and components, and involves planning multiple tasks, working to strict time constraints, transportation and a whole host of manpower issues. Competing in teams up to 10 students are required to construct a model aircraft in the 24-hour period. They need to ‘buy’ their raw materials (the components of a plastic kit). Parts are ‘bought’ with virtual dollars that can only be earned by completing specified tasks such as abseiling, rock climbing, orienteering problem solving etc. The ‘tasks’ are situated at map references within a 20 mile radius and two minibuses with drivers/trainers were available for each company. Other centre based tasks such as hill walking, high wire activities or completing an obstacle course need to be completed to earn ‘fuel miles’ for the buses. Students must also feed their teams while out on activities and can earn points by cooking for the staff who are there to facilitate and observe the activities and ensure the safety of the teams. Students must decide what is done, when and by whom through careful planning and the appropriate division of manpower. In fact, the trainers will happily drive in the wrong direction or take the wrong equipment if told to do so by the students or will stop the bus if the teams miscalculate and run out of fuel miles. Under these circumstances, on a cold spring night, teams soon learn the importance of careful planning and thinking ahead. Plans are presented to staff at the outset for approval.

Notwithstanding the obvious attractions of the outdoor activities, the focus remains very much on learning with extended review and feedback sessions after each activity. Review sessions are led by the trainers and prove very effective at teasing out the important lessons embedded in the assignments. The trainers refer back to the theory studied before the course and it then becomes much easier to place these ideas into context. At first, the university staff were surprised at the intensity of these reviews, clearly brought about by such enthusiastic engagement.

a. Assessment

Table 1. Assessment details: each module has 3 elements of assessment.

	D500	D517
1	A structured essay, to encourage students to research and report on leadership techniques.	Pre OMC Case study comprising a short paper and oral presentation (small groups – peer moderated)
2	At the end of the project, mentors write up their experiences in the form of a reflective critique.	Individual report on OMC experiences
3	The progressive appraisal system identifies strengths, weaknesses and growth from the perspective of both supervisor and subordinates.	Team exercise – create a video documentary on a specific topic of teamwork and leadership.

3 RESULTS FROM THE SURVEY OF PARTICIPANTS

The novel methods used in both modules have created a lot of interest, not least from prospective employers. Graduates recount how prospective employers often appear disproportionately interested in hearing about these activities during job interviews and claim that taking part has given them an edge in the employment market. It is difficult, however, to be objective about how effective the modules really are in achieving the intended learning outcomes. From verbal feedback and end of module surveys, there is no doubt that our students think the opportunities are invaluable. Both modules operate on the principle that leadership cannot be taught but has to be nurtured through experience.

To compare the two methods, a year-group of students on both modules were asked to complete surveys of their attitude to leadership issues both before (anticipation) and after the courses (reflection). The same questionnaire was used with both modules. In total 65 participants took part in the survey.

General questions elicited written comments. When asked what they hoped to gain from the modules before starting, many hoped to gain confidence and personal skills while others looked forward to actually experiencing management skills and gaining organisation abilities. A number also hoped to gain in confidence for interview situations they would face in the near future. The reflection surveys seem to indicate that these expectations were achieved and in many cases, exceeded.

A set of statements focused on students' emotional reactions, they are listed below.

1. I like to encourage others
2. I feel comfortable as a leader
3. I like to work in teams
4. I like to work alone
5. I am good at decision making
6. I am confident in my abilities
7. I am confident as a person
8. I listen to what others say
9. I am an organised person
10. I plan before doing things
11. I pay attention to detail
12. I am patient
13. I like to get on with things
14. I reflect upon what has occurred
15. I review the work I have done

It is perhaps not surprising that a group of high-flying finalists should respond well to leadership; this is certainly no cross-section of the general public. The surveys were completed at different times, so most students would not remember their answers to the anticipation survey and have to answer truthfully when reflecting. Of course, different students participated in each module. The anticipation surveys for both modules shows relatively few apparently introverted individuals, reluctant to be involved but despite the relatively high 'anticipation' scores, the collective trend for both modules was to a further increase scores after the module.

There is insufficient space in this paper to discuss all the results in detail but the charts, below show selected highlights. Each chart shows the responses for the two modules side-by-side; the mentoring-based module with the light bars. The darker bars behind refer to the residential course module. Each bar represents the percentage of students on each module who either agree or disagree with the statement – in the Anticipation survey (A=left bar) and in the Reflection survey (R=right bar) so an increase in positive answers or a decrease in negative answers from A to R suggests development. In most cases one observes that the neutral or semi-negative scores fall as these people shift to more positive scores to the right.

Question 1 (figure 2) considers aptitude to working with others: both modules require the student to take an active interest in the work of others but there is a fundamental difference that in D500, the mentors are required to encourage a team of younger students while the team activities on the outdoor course are all within the same peer group. Both modules show some development but the improvement is stronger in D517. It appeared that some pretty strong and lasting friendships grew out of the OMC activities whereas mentors are, by their very role, expected to remain quite detached from their mentees. It is always easier to encourage a friend.

Question 2 (figure 3) asks whether individuals are within their comfort zone in a leadership situation. Again, the results are encouraging showing that the experience has led to an overall improvement in confidence. In this case, the mentoring experience shows the greater development. This may be because the topic of this module (an engineering project) is more familiar than some of the outdoor experiences that are designed to stretch the participants' achievements in new areas. Nevertheless, it is quite common for a student to admit some trepidation at the thought of taking responsibility for a second year team in D500.

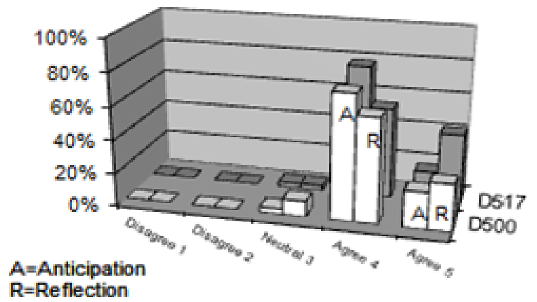

Fig. 2: I like to encourage others

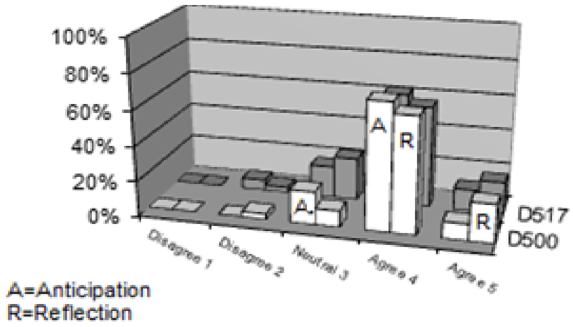

Fig. 3: I feel comfortable as a leader

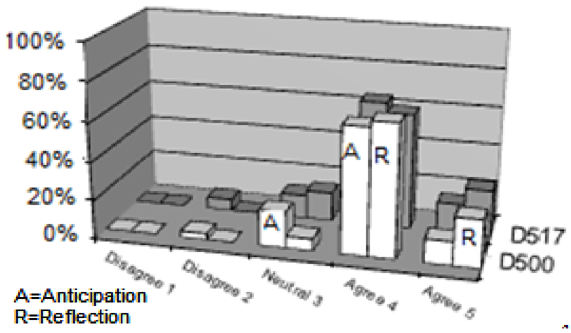

Fig. 4: I am confident in my abilities

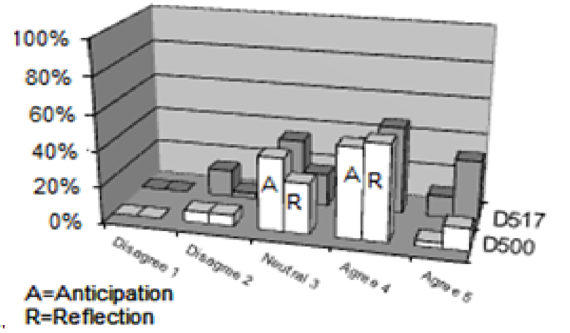

Fig. 5: I review the work I have done

Figure 4 looks at confidence; (question 6) Here again the mentoring module indicates the bigger gain. Perhaps there is truth in the anecdote that a person learns their subject well when they have to teach it to others, a feature of this module.

Question 9 (figure 5) shows the results for question 15 concerning the ability to reflect and review. The outdoor course seems particularly good at developing this important ability and approximately 20% of students recorded movement from one response category to the next. They reported that it was only after these sessions that their previous study on management topics back at university had started to appear relevant. One student commented in writing of the residential module "some of the most important and valuable lessons I have learned during my degree".

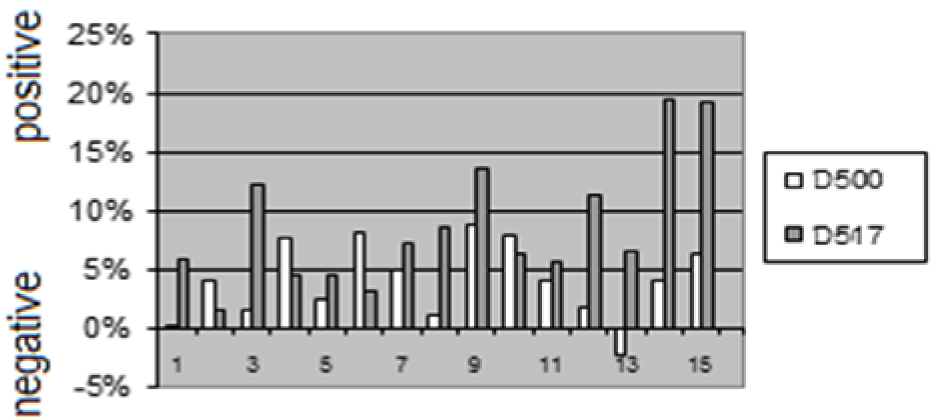

Fig. 6: Change analysis for all questions.

Figure 6 summarises the responses to all questions in numeric form where 5=strongly agree 4=agree, 3=neutral, 2=disagree and 1=strongly disagree. The chart shows the change in the group average scores before and after the modules. Of note, perhaps is one negative change for D500; question 13, “I like to get on with things”. There is no obvious explanation for this. The overall picture, however is of improvements across the board for both modules, which is very gratifying.

4 CONCLUSIONS

The world of employment training has proved an interesting and rewarding experience for both staff and students. There is no doubting the enthusiasm for this amongst these senior students who are focusing on their next career step into paid employments with considerable ambition. I doubt the courses would be so successful with a less well driven cohort. Indeed, one of the Lindley trainers commented that this group showed more enthusiasm than many groups of company executives.

The survey results suggested that both models are valuable. At present the two modules are offered as alternative options which are described to the prospective students in advance. Some people might find the content of one or other quite daunting and offering a choice prevents the possibility of an unhappy mismatch. While both modules appear to meet the objectives well, mentoring appears particularly strong in developing leadership and confidence while the outdoor management course excels in building teamwork and understanding theory through review and feedback; these, in fact were the areas that showed the biggest gains.

Furthermore leadership and team-building training provides a powerful added attraction to potential employers of engineering graduates.

Teaching the art of communication through drawing

PT Mylon
University Teacher
Multidisciplinary Engineering Education, The University of Sheffield
Sheffield, UK
E-mail: pete.mylon@sheffield.ac.uk

ABSTRACT

Engineering drawing is a form of communication. Sketching skills are vital for communicating ideas, and understanding of the principles behind drawing conventions is needed to ensure clear communication between designers and fabricators. However, students are losing that ability to communicate as universities move towards CAD-only courses. What is needed is a course that reflects the real-world relationship between drawing, sketching and CAD: the modern engineer sketches an idea, takes it into 3D CAD, then produces 2D manufacturing drawings where necessary.

An exercise was designed in order to teach sketching and CAD skills to first-year engineering students at The University of Sheffield in an industrially relevant context, with the focus on communication rather than conventions. Students were given novel 3D-printed shapes and asked to sketch the part using standard drawing conventions so that someone else could reconstruct it.

Each student then created a CAD model from someone else's sketch, providing written feedback, and produced manufacturing drawings using SolidWorks.

The method described in this paper has been shown to be an effective and relevant way for students to learn the principles of engineering drawing, sketching and CAD. Peer feedback was shown to be an effective learning tool for both parties.

Conference Key Areas: Engineering skills, Curriculum development

Keywords: graphics, CAD, peer feedback

INTRODUCTION

"The single biggest problem in communication is the illusion that it has taken place."[1] Engineering drawing is a form of communication. Manufacturing drawings communicate a designer's intent to the fabricator. When an engineer wants to communicate an idea to another engineer, the first thing they reach for is a pencil. It has also been suggested that sketching is a way of offloading the visio-spatial working memory [2], allowing more space for design thinking. It is thus an integral part of the design process. Despite this, mechanical engineering programmes are increasingly moving away from hand drawing and teach little sketching [3,4]. Students are also coming to university with poorer hand drawing skills and performing poorly in drawing courses that do exist [5]. Communication has been identified as something students in group design projects struggle with, because of a lack of common “design language” and “communicative tools” such as sketching [3]. Stacey et al. noted that while “freehand sketches are a fast and powerful medium for expressing design ideas… misinterpretation of sketches is a major cause of communication failure in design teams” [6]. For this reason, teaching of hand drawing skills cannot and should not be entirely replaced by CAD-only courses.

The emphasis in traditional drawing classes has been on adherence to strict conventions such as line widths, text height and hatching types. As engineering programmes move away from teaching hand drawing to focus on drawing interpretation [7] and CAD skills, even with the introduction of modern interactive teaching tools [8,9], the key concepts for drawing identified by academics and industry experts [10] still focused around particular conventions such as orthographic projection, how to section, dimension and annotate. While these conventions are undoubtedly useful in forming a clear common language, it is important that the emphasis is placed on the communication itself rather than the conventions. With the advent of CAD and the rapid pace of technological development, engineers must understand the fundamental principles behind the conventions in order to be able to use them flexibly across different media and in interdisciplinary contexts. Otherwise, they are likely to discard conventions altogether and fall into ambiguous communication.

Both the traditional method and the CAD-only method fail to reflect the real-world relationship between drawing, sketching and CAD. Traditional courses tend to start with pencil drawing on drawing boards, with sketching and CAD introduced later, once “the foundations” have been laid down. The modern engineer sketches an idea, takes it into 3D CAD, then produces 2D manufacturing drawings where necessary. In this paper, it is argued that drawing and CAD teaching should reflect this process more accurately, rather than being taught in isolation, and should emphasise the development of communication skills. A prototype exercise is detailed and analysed.

1 BACKGROUND

In September 2016, the first cohort of a new MEng Engineering programme began their studies at The University of Sheffield. The programme was intended to be interdisciplinary, covering mechanical, civil, electrical and electronic, and chemical and biological engineering amongst others. This represented an opportunity to look again at the teaching of engineering drawing and computer-aided design (CAD). Through discussions with the relevant teaching staff across the faculty, it became clear that the main requirements common to all disciplines were for students to be able to sketch, to understand the relevant drawing conventions, and to be able to use CAD.

In the Mechanical Engineering department, the teaching had previously consisted of a series of lectures accompanied by hand drawing exercises, and a separate CAD course. This reflects historical engineering practice, where draftsmen would produce manufacturing drawings by hand (or later in 2D CAD) and engineers might separately produce 3D CAD models for use in Finite Element Analysis.

However, modern design and manufacturing tools, and the widespread availability of prototyping tools such as 3D printing mean that the modern engineer approaches the design-manufacture process very differently (see Figure 1). After an initial (sketched) concept, products may be directly designed within CAD, the idea taking shape as they are drawn; in civil engineering, the model may be created in Building Information Modelling (BIM) software so that it links with other design information; and crucially, parts can in some cases be manufactured directly from 3D models, bypassing the 'drawing for manufacture' process altogether. Where they are used, manufacturing drawings tend to be produced in CAD packages from the 3D model, and are increasingly used purely as a reference against which to evaluate the finished article, rather than the instructions on how to produce it. The use of templates for both drawing sheets and drafting standards has reduced the need for engineers to commit to memory entire drafting standards, allowing a focus on the fundamental elements.

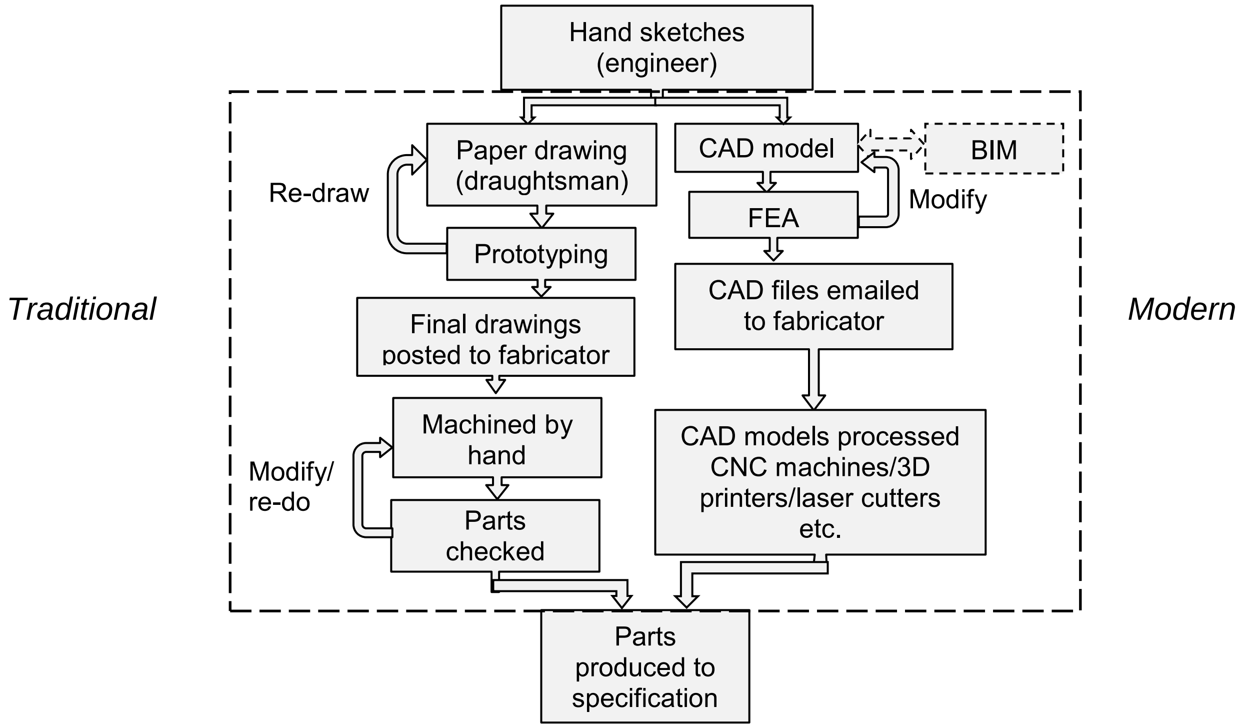

Fig. 1. Comparison of traditional and modern design processes

2 DESIGN OF LEARNING AND TEACHING ACTIVITIES

In order to more accurately reflect the interplay of sketching, CAD, and manufacturing drawings, and the importance of communication above the recall and application of specific drafting standards, an exercise was designed for 35 first-year engineering students at The University of Sheffield. By the end of the exercise, the students were expected to be able to:

- Communicate engineering concepts through sketching
- Use accepted drafting conventions to describe an object geometrically
- Interpret an engineering sketch and reproduce the object in CAD
- Produce part and assembly drawings in CAD
- Select and correctly mark appropriate tolerances for a hole and shaft based on a specified fit type

Each student was randomly assigned a 3D-printed part from a range of nine, consisting of three mating pairs and a three-part assembly. The parts are shown in Figure 2. Including physical interaction with machine parts in drawing classes has been trialled elsewhere [5, 11] and was found to improve students' spatial awareness and engagement. Each of the parts was a novel shape drawn in SolidWorks® using a combination of simple and complex operations. The use of novel shapes rather than existing components was intended to remove the ability of students to recognise the object and thus fill in missing information from memory. This simulates real-world conditions where a novel component is being designed.

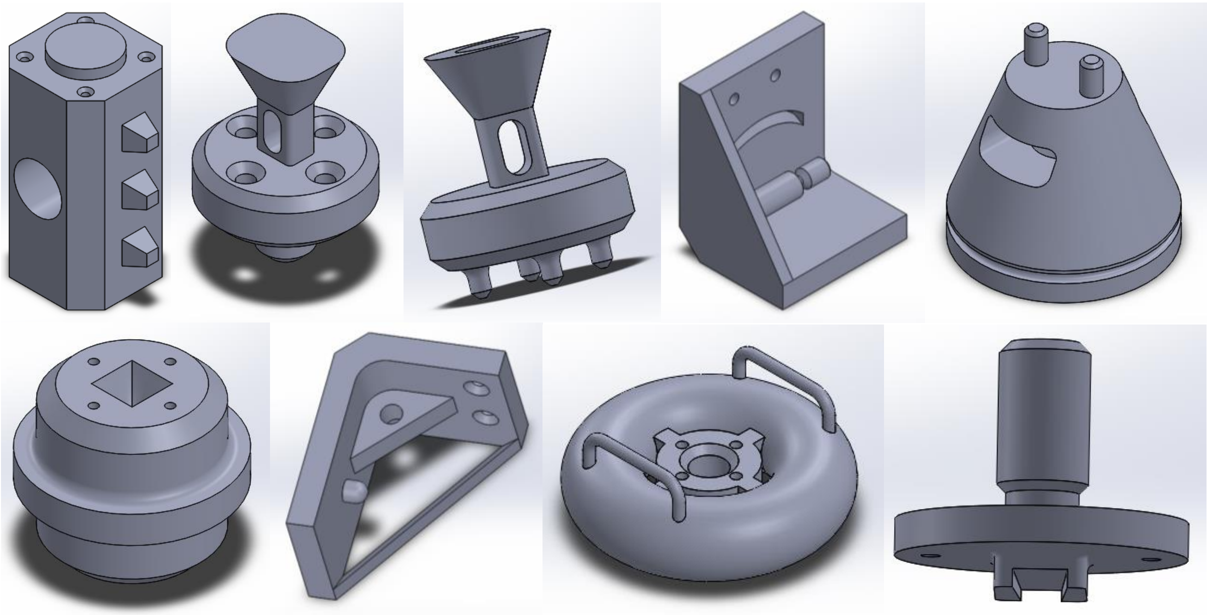

Fig. 2. CAD models of parts used in the exercise

Students were allowed to take the part away and told not to show it to anyone, but to sketch the part using standard drawing conventions and fully dimension it, using notes to clarify where necessary, so that someone else could reconstruct it. Students had previously attended a lecture and practical class where instruction on drawing conventions was given and students had an opportunity to practise sketching and receive feedback.

The students' sketches were collected and redistributed at random to those with a corresponding mating part. After some CAD tuition, they were asked to create a 3D model from the sketch and provide written feedback to the sketcher, focussing on whether the information had been communicated clearly. At this point, they were allowed to discuss the model with their partner and receive clarity on points of confusion. They were then asked to modify their model in light of the discussion and share the finished part with their partner.

Although some efforts have been made to integrate the teaching of hand drawing and CAD at other universities [5], this approach goes further, linking the two parts in a single exercise via an interpretation task that forces students to consider the viewpoint of those to whom they must communicate, and teaches the value of clarity and a common language in the form of conventions.

After further teaching on drawing for manufacture and basic tolerancing, they were each asked to produce manufacturing drawings of the two mating parts using SolidWorks, including an assembly drawing with a Bill of Materials. They were also given a fit for the mating hole and shaft (based on descriptions in [12] e.g. "loose running fit"), and asked to add appropriate tolerances to the relevant dimensions on the part drawings.

3 ASSESSMENT

Students were asked to electronically submit a portfolio containing their sketch, feedback on their partner's sketch, CAD models before and after discussion, and part and assembly drawings. The marking scheme is shown in Table 1. It can be seen that clarity and completeness feature prominently, and less weighting is given to adherence to specific conventions.

Table 1. Marking scheme for the exercise

Task	Weighting (%)
Sketch	**15**
How well does it convey the necessary information about the part?	
• Clarity	5
• Completeness	5
• Use of space	1
• Proportion	1
• Correct use of conventions (orthographic/isometric, sectioning, centre lines, dimensions etc.)	3
First model *How well does it represent the information in the sketch?*	**15**
Feedback *Does it identify all the issues with the part (clarity, completeness, use of space, proportion, etc.)?*	**10**
Second model	**20**
How closely does it replicate the part?	
• Basic features (extrude, revolve etc.)	10
• Holes (location, countersinking etc.)	5
• Complex features (loft/sweep etc.)	5
Detail drawings (each)	**15**
• Completeness (no. of views, hidden detail, full dimensioning)	6
• Clarity (details not overlapping etc.)	2
• Correct tolerancing of hole/shaft mate	5
• Use of space (sensible scaling)	1
• Title block	1
Assembly drawing	**10**
• Use of space	2
• Clarity	2
• Balloons	2
• Correct BOM	3
• Title Block	1

4 RESULTS

By the end of the course, most students were able to demonstrate an ability to communicate clearly and an understanding of basic engineering drawing concepts. Examples of original sketches and final CAD drawings are shown in Figures 3 and 4, along with the feedback provided by another student on the sketch.

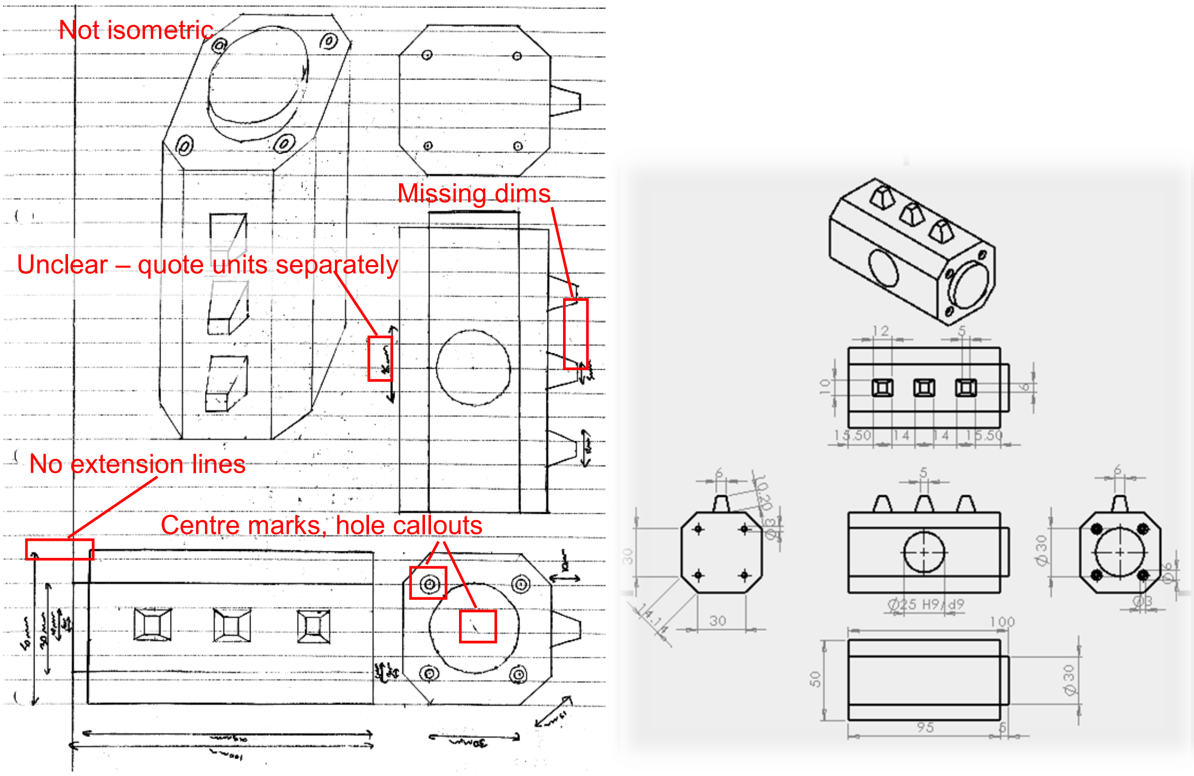

Fig. 3. (a) Original sketch with main errors shown; (b) final CAD drawing

Excerpts from the student feedback provided on the sketch (Fig. 3a):

"The sketch made the shape of the object clear… however whilst drawing I couldn't place the smaller details (the protrusions and holes) on the object due to a lack of centre lines and dimensions stating where on the object they should be. I had to guess where the holes went... Hidden lines would have helped identify how far the holes go into the shape along with their respective dimensions... Dimensions were sometimes ambiguous as some were similar and didn't have projection lines."

Excerpts from the student feedback provided on the sketch (Fig. 4a):

"… showed a clear understanding of how to… clearly convey how the object would look in real life… a good use of different types of lines to represent the interior detail… some confusion with the scale… and I had to estimate the distance of the innermost indents at the bottom of the shape… some issues with reading the measurements [which are not] connected directly to the ends of each part… some measurements were not provided… I would recommend double checking whether the dimensions at the top of the front-on view add up, labelling centre lines and the height of the cylinders on top of the shape as well as the distance between them, and including the dimensions of width of the removed square on the front view… rather than on the view from above… isometric view would be desirable, however it is not essential as the overall shape was clear. The information provided about [thread] proved to be especially helpful."

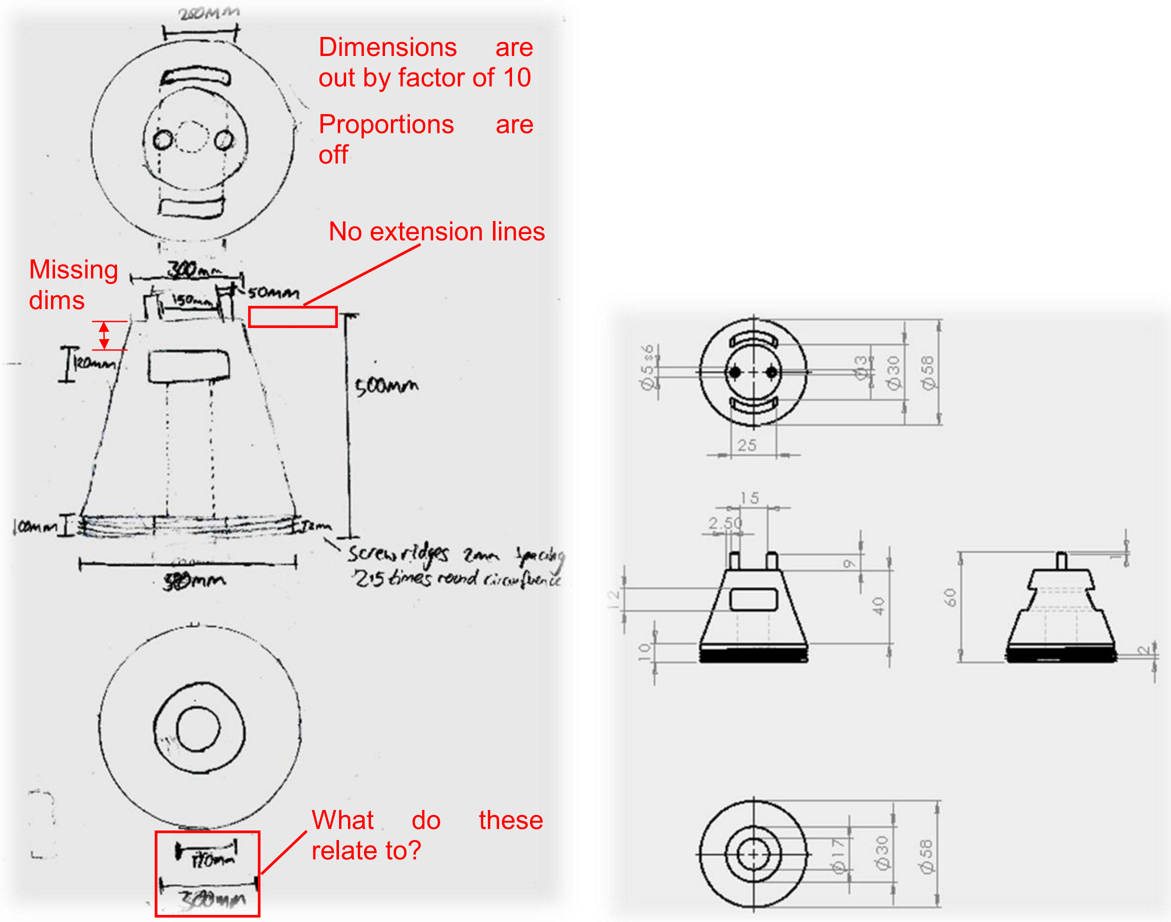

Fig. 4. (a) Original sketch with main errors shown; (b) final CAD drawing

It is clear from the improvement in clarity and completeness from the sketches to the final drawings (leaving aside the obvious advantages given by using CAD), that most students had achieved the intended learning objectives. The quality of feedback provided also shows that through the experience of using the sketches to create a CAD model, most students grasped the salient points of what makes a good engineering drawing and why clear communication matters when specifying for manufacture.

5 EVALUATION

This exercise reflects real-world use of CAD and drawing, and places the emphasis on developing the "communicative tools" and common "design language" [3] that students are missing. The use of sketching allowed them to focus on correctly using drawing conventions to communicate, rather than on drawing neatly or with the correct pencil. These skills should be transferrable to other standards (such as civil, chemical, or electrical drawing) since students understand the purpose of drawing rather than just memorising rules. The process of interpreting and feeding back on the sketches also gave the students the opportunity to understand the impact of good and poor practice on the effectiveness of communication, and to reflect on their own submission. The use of 3D-printed parts allowed the students to relate their drawings to a physical object, while also giving the flexibility to create complex, novel geometry that could not be replicated by traditional methods.

6 CONCLUSIONS AND FURTHER WORK

The method described in this paper has been shown to be an effective way for students to learn the principles of engineering drawing, sketching and CAD in an industrially relevant context. Peer feedback was shown to be an effective learning tool for both parties.

In the next iteration of the exercise, students could print parts from their models to be able to compare visually with the originals and understand how differences arose, which would be a useful form of feedback. Alternatively, augmented reality facilities at the University may be used to allow students to visualise the model in 3D and compare that way. This will additionally broaden the students' understanding of the uses of CAD modelling and increase engagement with the exercise.

The cohort used for this exercise was much smaller than those of Mechanical and Aerospace Engineering to whom such courses have previously been delivered. In order to roll out this exercise to those students, a peer review method for marking will be trialled.

ABSTRACT

In this article, we discuss the development of a specific entrepreneurship training programme and its integration into traditional doctoral education. We present a description and reflection on our new entrepreneurship training programme which is specifically designed for PhD students in engineering sciences. We propose a twofold approach: training programme development which takes into consideration, not only the initial skills level of participating students, but their future career perspectives as well. We define four skill development levels which are differentiated by specific requested learning outcomes. As a conclusion, we provide reflections on the future perspectives of entrepreneurship education in this specific context.

Conference Key Areas: Curriculum development, Engineering skills

Keywords: Doctoral education, Engineering science, Entrepreneurship training

INTRODUCTION

Doctoral students' education aims to develop highly specialised theoretical knowledge in students' research fields, as well as developing their skills and competencies in researching to help them better prepare their thesis [1]. These abilities are indispensable, not only to successfully complete their doctoral studies, but also for performing well in an academic career. However, only a minority of PhD students in engineering sciences will have the possibility to pursue an academic career in their research domain. According to the latest survey, the proportion of graduate engineering PhD students who started an academic career is in constant decline (from 52 % in 2010 to 43 % 2013) in France. The majority of them will make their career in industry and work in a business environment [2]. In this context, entrepreneurship education is viewed as a real facilitator in the transition of a constantly growing proportion of graduate PhD students from academic education to a work environment [3].

1 ENTREPRENEURSHIP EDUCATION

1.1 Entrepreneurship education for PhD students

Entrepreneurship education was introduced into the curriculum of French higher educational institutions relatively late, only over the past two decades. Its introduction was strongly encouraged and supported by the government in order to stimulate entrepreneurship activities and create employment [4]. However, the integration of entrepreneurship education in doctoral education programmes is still not generalised and depends mainly on institutional decisions. This is quite surprising despite the numerous benefits of these programmes for PhD students, industrial business organisations and higher educational institutions.

For PhD students, entrepreneurship education could appear as the cornerstone of their future employability: if they are to work in an industrial or business organisation, they have to possess not only well founded technical skills, but also business and entrepreneurship skills in order to allow them to operate successfully in this new environment. These ‘non-technical’ skills and competencies, often considered as secondary or complementary, have become vital for graduate doctoral students to acquire for when they start their career in industry. The possession of these transferable skills and competencies can give considerable advantages for them in the recruitment process.

For industrial organisations entrepreneurial skills and competencies have an important place in their skill requirements and are viewed as one of the key competencies nowadays. It is obvious that these skills and competencies are particularly important to build a solid entrepreneurial orientation which consists of innovativeness, proactiveness, risk taking, competitiveness and autonomy [5]. In a competence based market competition [6], employees’ competencies are considered as one of their most valuable assets for them to be able to develop new and innovative products. The lack of these skills and competencies could considerably reduce their economic performance and their capacity to attain sustainable competitive advantages. This is even accentuated in industry where engineers’ skills and competencies have a huge influence on the ability of organisations to create significant value added products and services.

From an academic perspective, the development of entrepreneurship education for engineering doctoral students has become an important issue. Several studies [7, 8, and 9] pointed out the positive effect of entrepreneurial education on the development of students’ business skills and competencies, and also on their innovation capacity [10, 11]. Entrepreneurship education has numerous short-term effects, such as the raising of entrepreneurship awareness, elevating the understanding about enterprises, allowing for the development of an entrepreneurial mindset or an awareness concerning the attitudes and intention toward entrepreneurship etc. [12]. Furthermore, there are several widely recognised positive long-term effects of entrepreneurship education on society, such as developing an idea and patents generation, allowing for enterprise growth and increasing job creation which motivates the expansion of entrepreneurship education [13].

1.2 Doctoral entrepreneurship education programme in France

Despite its long-standing needs, entrepreneurship education is a relatively new phenomenon in PhD students’ education in France. It was introduced into doctoral training only six years ago with the participation of a limited number of post-graduate engineering schools. With the support and encouragement of the government, it was launched by the CDEFI (Conference of Deans of French Schools of Engineering) in the framework of a specific doctoral training programme after a two year experimental period (from 2011 to 2013) when the programme was tested by nine engineering higher educational institutions [14]. Since its introduction, the number of participating institutions has seen an exponential growth, as 26 engineering schools and 30 doctoral schools participate in this programme today [15]. This doctoral programme is open for all doctoral students, independent of their scientific disciplines, and it is not reserved solely for engineering doctoral students. However, on the national level, 50% of the participants are doctoral students in the domain of engineering sciences. This high participation of engineering doctoral students is mainly explained by the fact that engineering schools in France traditionally have a strong relationship with industry which gives them a good vision about what the industry needs and its requirements for skills and competencies.

The main objective of this programme is the development of the skill and competency requirements which doctoral students need in order to improve their employability which will allow them to work in a real business environment. As we mentioned before, the majority of PhD students in France pursue their career in an industrial business environment. However, contrary to other European countries (e.g. Germany, UK), PhD graduation is not really recognised by French industrial business organisations. In this context, this doctoral training has a specific purpose of making the recruitment of graduate PhD students more attractive in the labour market. According to a recent study [16], graduate PhD students have difficulty identifying accessible positions and the skill and competency requirements of industry outside of their research and development activities. This programme could help them to better understand the concept and practice of industrial business organisations, and not only better identify the required skills and competencies of the industry, but to take advantage of them.

1.3 Skills development

The definition of the required skills was based on the referential list ‘DocPro’ which was co-created between the national association of PhD students (Association Bernard Gregory), the CPU (Conference of University Presidents) and the MEDEF (French Business Confederation) and included 24 skills over four domains [17]. There is a well-defined correspondence table between the referential ‘DocPro’ and the skill definition of the doctoral entrepreneurship programme [14:15] to help students in the evaluation of their skills.

The required skills in the doctoral entrepreneurship training are divided into four principal categories with several components in each of them (Cf. Table 1). The first category is related to the engineering PhD students’ ability to understand business concepts and practices. The second category is associated with project management and the capacity to work independently. The next category is composed of scientific and technical knowledge from the problem definition to the solution. The last category includes several social skills, such as interdisciplinary communication or language skills. For the obtainment of their certificate, students have to acquire at least 8 skills from these 15 skills by the end of the programme.

At the beginning of the training, as a part of the selection process, each engineering PhD student is asked to make a self-evaluation. Considered as the basis for the personalised programme construction, this self-evaluation is very important in defining what skills they need to develop. The result of this self-evaluation is very heterogeneous, as there is a huge difference in skill development in each discipline and even between the different fields of engineering science [18]. Furthermore, there are large divergences at a personal level, as each engineering PhD student has his own personal academic and work experience.

Nevertheless, the selection of candidates is not based on students' initial skills, but essentially on their motivation and their capacity to integrate into a business work environment. Also, the engagement of candidates on this two year doctoral entrepreneurship education training is an important criterion of the selection process. Given the fact that this is highly personalised doctoral training, it requires an important investment from the institutions. For this reason, requiring a high level of students' engagement could limit abandonment and failure.

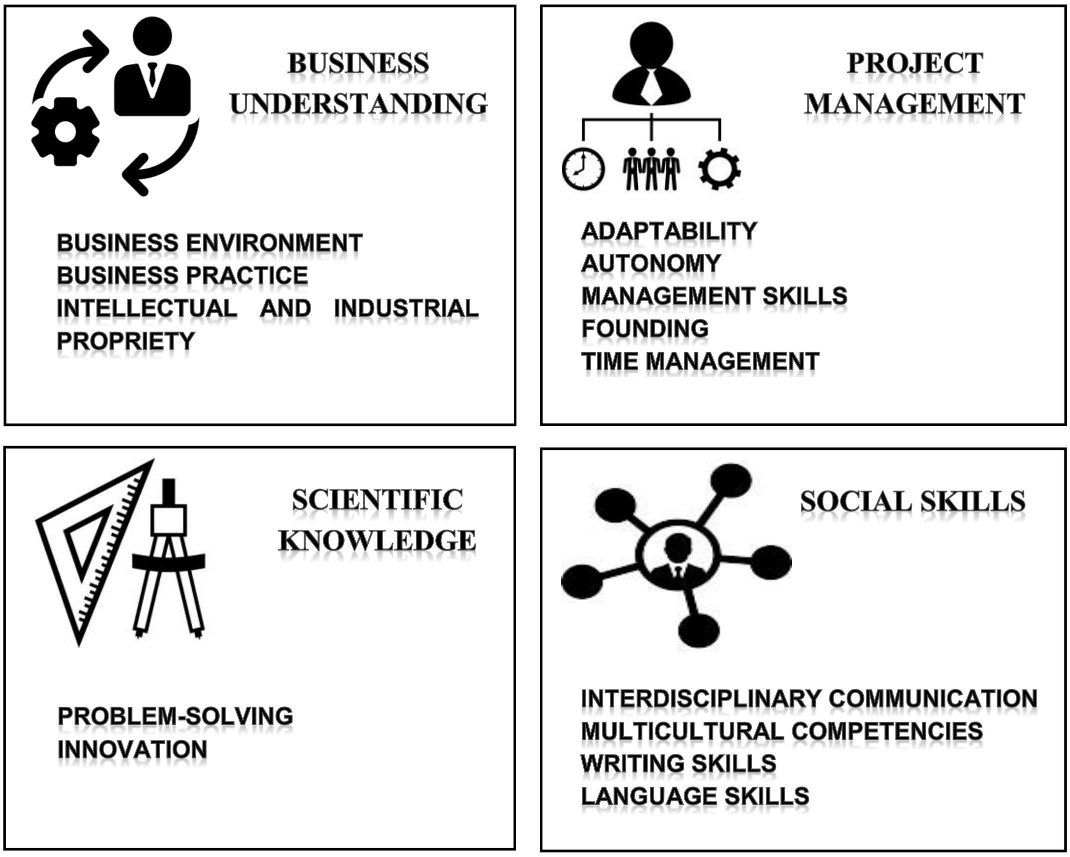

Fig. 1. Entrepreneurial skills development (Adapted from [14])

2 CURRICULUM DESIGN

In our engineering school, we have recently introduced a certified and adjusted two year entrepreneurship education programme. The curriculum development of the programme was based on the official recommendations of the CDEFI following the general framework of PhD programmes, which was designed to facilitate doctoral students' integration. This new entrepreneurship education programme is available for doctoral students who have successfully completed their first-year PhD studies and who have a proven record of engagement in their studies. We outline that students' engagement is particularly important in this programme for two main reasons: firstly, it is the longest doctoral programme proposed in our engineering school (lasting over two academic years) and secondly, it requires an important investment from our institution.

We have developed a highly personalised programme for our PhD students, which takes into account:

- Students' self-evaluation about their existing skills when they enter the programme and
- Their career prospects and the principal skills that they would need for their future professional activities.

As the participating PhD students are drawn from diverse engineering and scientific disciplines, they have very different skill sets when entering our entrepreneurship educational programme. Also, they have various career prospects depending on their personal preferences and opportunities. As we have a really heterogeneous participating population, we have applied a twofold approach (Cf. Figure 2) in the curriculum design, which simultaneously considers their initial skills level and their future working environment.

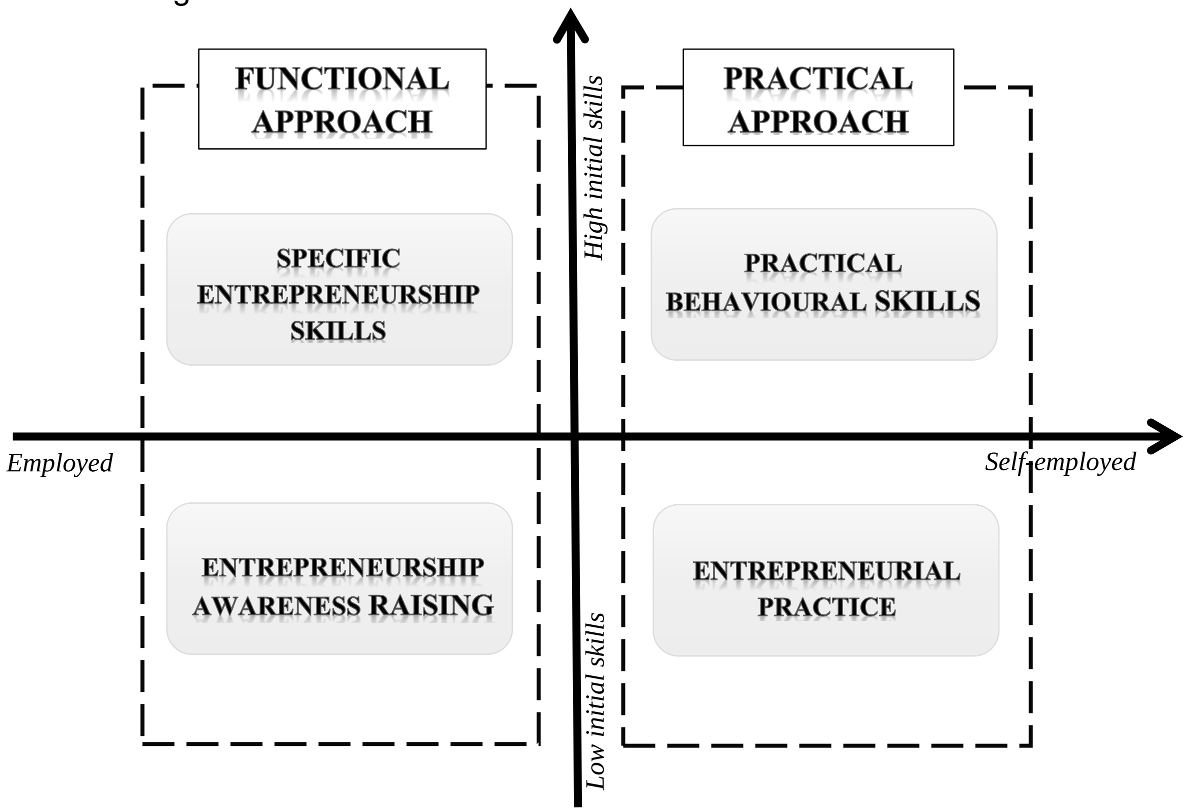

Fig. 2. Conceptual framework of the entrepreneurial programme development

2.1 Functional approach

We follow a functional approach in the curriculum design when participating students have a career desire to work in a business and industrial organisation. In this case, our main objective is the transmission of functional skills and knowledge to them. This approach is based on the development of general and specific business skills and depends on the participating student's skill development needs and requirements. Students have the choice of a large variety of modules which last a maximum of one semester and do not require long term engagement. We distinguish between two levels of skills development:

2.1.1. Entrepreneurship awareness raising

At the first level, we provide mainly theoretical knowledge and basic skills for raising their entrepreneurship awareness by giving them an insight into the life of businesses, in order for them to understand how it works. In this category, we have participating PhD students with a low level of initial skills on entering the programme. Typically, these participating students have a high level of scientific knowledge and skills, but have had a lack of opportunity to learn business subjects during their previous studies. For this reason, they generally need to acquire solid basic knowledge and skills to be able to understand and to be ready to work in a business environment.

2.1.2. Specific entrepreneurship skills

At the second level, we take into account students' special interests and preferences and aim to develop entrepreneurship skills and competencies by focusing on what would be principally useful for their future professional careers. At this level, we have participating doctoral students who possess strong basic business skills and understanding. They are interested to be involved in specialised modules relevant to their particular, and often well-defined, objectives. Usually, they are enrolled in this programme to acquire expertise in specific subjects, in most cases related to their scientific and research activities, in order to enhance their potential career opportunities.

2.2 Practical approach

For participating PhD students who have the intention, in their short or long term career, to set up their own companies, we applied a practical approach in the curriculum development. The principal objective of this approach is the transmission of practical and behavioural competencies in order to teach them how to develop entrepreneurial activities. We provide a highly specialised and individualised entrepreneurship learning programme which includes the creation of a new business by doctoral students. In this case, participating students have to undertake the PBL based entrepreneurship modules which are longer than the modules of the functional approach and need two to four semesters of continuous work and engagement. It is manifest that this practical approach requires a clear long-term vision, strong engagement and perseverance from them. They have to be highly motivated to accomplish these modules in parallel to their research and scientific activities, especially in the final year of their PhD studies. In this approach, we differentiate two levels of skill development according to the objectives of their entrepreneurship project.

2.2.1. Entrepreneurial practice

At the basic level, they are required to develop an entrepreneurial project as a member of a multidisciplinary team composed of graduate and postgraduate students of other engineering and non-engineering domains. The main objective of this entrepreneurial project is to learn how to create their start-ups. Despite the fact that every year at the end of the module some of these projects are transformed into a real business, the vast majority of them are only created to achieve the learning outcomes. Participating PhD students generally have a long-term career goal to create their own companies. However, they would like to start their career as an employee in an industrial business organisation in order to gain initial real work experience.

2.2.2. Practical behavioural skills

At the advanced level, PhD students develop their own business based on their technological invention or pattern. The principal objective of this level is not only to learn to lay the foundations, but also to create their real ventures. This level requires a particularly high level of engagement from participating students. At the end of our two year training programme, these students have the possibility, after finishing their PhD studies, to enter our engineering school's incubator and continue their project. During their entrepreneurship programme, they receive regular tutorials from the facilitator of the incubator. Also, they have the opportunity to participate in the diverse activities organised by the incubator which can facilitate their integration to the incubator's community.

As it was presented in the last paragraphs, we have designed the curriculum of our entrepreneurship education programme based on four differentiated learning objectives. The implementation of this programme requires the cooperation between teachers in management domains, research laboratories, our school's incubator and our industrial partners. Teachers in management and researchers in engineering were particularly involved in the development of the functional skills. The transmission of behavioural skills and competencies was carried out essentially by the help of our incubator and industrial partners.

CONCLUSION

Providing engineering PhD students with a well-adapted and valuable entrepreneurship education, alongside with its incontestable and numerous benefits, remains an important challenge today. Given the fact that the vast majority of PhD students will progress to a career in industry, entrepreneurship training opportunities for post-graduate students in engineering sciences will be in a growing demand over the next decade. However, the integration of entrepreneurship training programmes within the framework of doctoral education is not really prevalent, and only a very low percentage of engineering PhD students could benefit from it today in France.

Our engineering school has decided to take the lead in developing a tailored entrepreneurship training programme to increase doctoral students' employability. The introduction of this programme was appreciated not only by doctoral students, but also by their research laboratories, incubators and industrial partners and it has developed a thriving cooperation between them. Our first experiences confirm, from the abundant number of candidates, doctoral students' awareness of the benefits and usefulness of this programme. However, despite the raising need from students, it is available only for a limited number of doctoral students. As a future perspective, it would be beneficial to make it available for each motivated PhD student.

We have adopted a double approach in our programme which was useful for participating PhD students to receive a better adjustment and personalisation of their learning objectives. Students have a choice between four different learning objectives in relation of their future perspectives. It would be interesting to explore the applied teaching methods in each category and investigate what the most adapted methods are. It could provide us with useful information in choosing the best methods and ameliorate our curriculum.

ABSTRACT

From society and industry, there are increasing requirements for skilled and well-educated engineers who can develop new solutions through innovation and this have pushed universities to meet these requirements by having an increasing focus on developing innovation and entrepreneurship programmes within Engineering Education. Furthermore, there is also a demand for the graduates to be able to work multidisciplinary and to be able to use generic skills in their work. In this paper, the research question is how to enhance innovation and multidisciplinary competences of engineering students? This is a central question in order to educate engineers that can create sustainable solutions for the environment, for products and to secure future workplaces. In this paper, a new mandatory course for Bachelor of Engineering students at the Technical University of Denmark (DTU) “Innovation Pilot”, will be described and how the challenge to improve innovative competences and the ability to work in multidisciplinary teams with engineers from other disciplines are solved. Results from a survey regarding the students’ innovation competences and interdisciplinarity show that we have succeed in creation of understanding of what innovation is. However interdisciplinary is still difficult for the students to handle.

Conference Key Areas: Skills and Engineering Education

Keywords: Entrepreneurial minds-set, multidisciplinary teams, preparing professionals

INTRODUCTION

From society and industry, there are increasing requirements for skilled and well-educated engineers who can develop new solutions through innovation and this have pushed universities to meet these requirements by having an increasing focus on developing innovation and entrepreneurship programmes within Engineering Education [11]. Furthermore, there is also a demand for the graduates to be able to work multidisciplinary and to be able to use generic skills in their work [2].

The aim of this paper is to address the research question "How to enhance innovation and multidisciplinary competences of engineering students?" This is a central question in order to educate engineers that can create sustain solutions for the environment, for products and for securing future workplaces. In this paper, a new mandatory course for Bachelor of Engineering students at the Technical University of Denmark (DTU) called Innovation Pilot, will be described and how the challenge to improve innovative competences and the ability to work in multidisciplinary teams with engineers students from other disciplines is solved.

1 BACKGROUND FOR FOSTER INNOVATION IN EDUCATION

Innovation can be defined in many ways and in general, innovation can be seen as the process of translating an idea into a products or service which creates value for someone or something. Business is an important factor as innovation includes an economical aspect and can be seen as the result when new ideas are matured and marketed by a company in order to satisfy the needs and expectations of the customers [9].

A number of conceptualized definitions and theoretical approaches have led to several attempts to understand innovation competency. However, the definition varied considerable with different perspectives and approaches [11]. Innovation competences involve a wide range of human abilities and processes such as personal ability (in finding real-life problems and formulating research questions), interpersonal ability (by being open and responsive to diverse perspectives and intentionally constructing collaborative relationships) and implementing ability (by effectively implementing their ideas in useful projects) [11].

Interdisciplinary competences are necessary to manage innovation activity as well as there is a need for the engineers to have knowledge and understanding of other professions involved in the creative and innovation process [7]. Nowadays it is a critical job requirement to be able to work on flexible and always-changing teams and furthermore also to have the capability to recognize an interconnection among a broad range of activities.

Working with innovation requires enhancing of the students skills in creativity but also to give the students higher confidence to deal with uncertainty, ambiguity, and risk-taking [4].

Active learning education aims at providing the students with the opportunity to think critically and through a series of activities that help them to prepare for challenging professional situations which may involve evaluation, problem solving and critical reasoning skills. Problem-based learning is a well-known approach by using a problem solving approach as well as motivating and engaging the student in the learning process [5].

1.1 CDIO as a teaching paradigm

In 2011, the CDIO (Conceive-Design-Implement-Operate) syllabus was updated to version 2.0 [1]. Particularly attention was given to innovation, invention, internationalization and sustainability.

In the Bachelor of Engineering educations at The Technical University of Denmark (DTU), the CDIO-approach to Engineering Education is implemented as the overall teaching paradigm [2].

In September 2014 the first version of the new developed CDIO-based diploma (B.Eng) programs were launched at DTU. The most significant new activity in the education was the introduction of a common 10 ECTS compulsory course in innovation in the later part of the programs named Innovation Pilot. The idea behind this course is to give students the opportunity to collaborate on inter-disciplinary real-life projects. This course strengthens not only innovation skills but personal and interpersonal skills as well [8].

2 THE COURSE INNOVATION PILOT

The outline for the course Innovation Pilot is that the students work in multidisciplinary teams with specific real-life challenges offered by the involved companies.

The companies provide open-ended projects which take a starting point in actual challenges observed by the company. The company is the problem owner and the students should involve the context reality of the company in solving the challenges. The students are responsible for finding ways to apply their unique skills and knowledge to create value in the projects.

The Innovation Pilot course is offered three times a year, twice in the semester periods of 13 weeks and once as an intensive summer course of 6 weeks. At DTU there are 17 study programmes involved and it is expected that approximately 450 students from these 17 study programmes will attend the course during each spring and winter semester. At the beginning of the course, the students are divided into smaller units of up to 60 students running in parallel. Teams are formed so they consist of 4-6 students within a minimum of two disciplines present. The teams are assembled with different competences to be used for the handling the challenge provided by a company.

There are no traditional lectures in the course so the students are expected to have prepared themselves before coming to the class by e-learning. The e-learning material consists of short videos, documents and papers all available at the course site. E-learning gives flexibility and removes the traditional lecture. This is to optimize the time the students have to work together (one full day a week) and to allocate time for facilitation. All the way through the course, the students work on creating prototypes in the university's workshops facilities.

The course Innovation Pilot is fitting nicely within the framework in CDIO. The course is given for the students during the last semesters of their education and combined their independent use of the disciplinary knowledge they gained with going through all the phases in the CDIO process; Conceive-Design-Implement-Operate. The last phases Implement and Operate in CDIO can be hard to address in an educational setting. In Innovation Pilot the students work also in those phases through the outline for the course where the students work in multidisciplinary engineering teams with a specific open-ended challenges offered by industry companies. The students involve the reality of the company when solving the challenges. Students are introduced to real life problem by direct involvement of enterprises which are engaged from the beginning of the course to propose challenges for the students.

The students attending the course come from 17 different study programmes and they have different experiences working in multiple disciplinary teams and with innovation. Depending on the case some students can easily adapt their educational background with the case work while others find it more difficult. From the course responsible there is focus on that the company challenges should be relevant for engineers and have a technical aspect. Furthermore, there is a focus how student with different educational backgrounds can use each other expertise and also use of generic skills in working with the company challenge.

The teaching in innovation pilot is based on the active learning method “problem based learning” with use of blended learning/flip the class room and workshops and team work. Furthermore, peer-feedback and pitches are used as part of the teaching.

2.1 Course design and learning processes

At the course innovation pilot, the Double Diamond model is used to support the innovation process. Double Diamond is a process model created by Design Council, a British organization, in 2005 [3] and it presents four main stages across two adjacent diamonds. The first diamond in the Double Diamond model concerns exploration of the problem and understanding of the problem. The second diamond is the problem solving phase. Each of the four stages is characterised by either convergent or divergent thinking. The four stages are:

- Discover –identify, exploration research and understand the initial problem.
- Define – limit and define a clear problem to be solved.
- Develop – focus on and develop a solution.
- Deliver – test and evaluate, ready the concept for presentation for the company

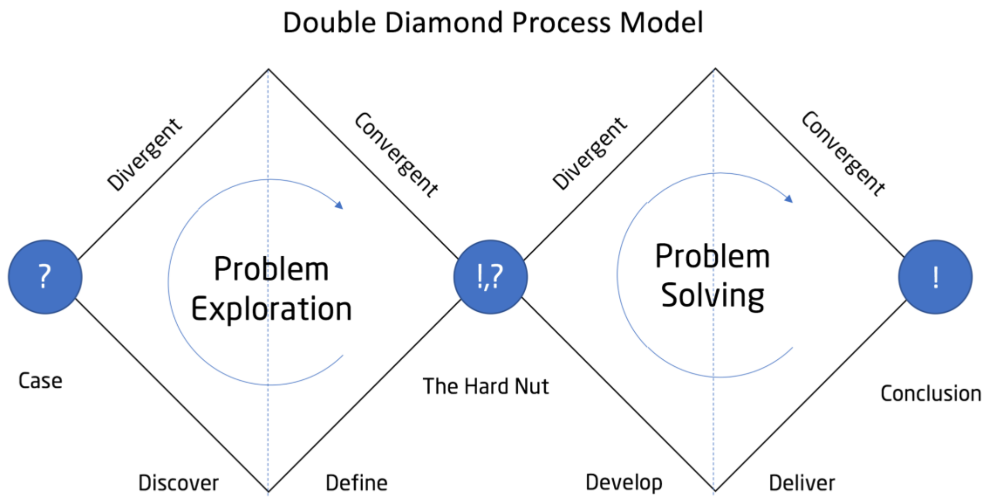

Fig. 1. Made by inspiration from the double diamond process model (Design Council, 2005 [3])

During the course, the students run the innovation process twice in two so-called loops, both involving company challenges. In both loops, the students conduct an innovation process structured according to the double diamond model (*Fig. 1*). The first loop takes four weeks and it is a training loop where the students get to know how to work with the double diamond process model with additional methods and tools. In the second loop, 2-3 teams of students work with the same challenge provided by a company and the process is structured as in the first loop, but it is now more up to students to plan their work. The second loop takes 8 week with 3 weeks dedicated to exploring and defining the problem (the first diamond in Double Diamond) and 5 weeks dedicated to problem-solving and prototyping (the second diamond in Double Diamond) [6].

3 APPROACH AND FINDINGS

Since spring 2016, the course innovation pilot has been running three times, and the number of students and company involved has increased over time. In spring 2016, the course ran for the first time and it was an elective course with 42 students. The second time the course was up scaled and had become a mandatory course with 233 students enrolled and at the third time, 272 students were enrolled. The companies involved in the course are mainly small-medium sized enterprises and typical engineering companies [6].

When the course was running in autumn 2016, a questionnaire was made to evaluate the students perception of innovation and interdisciplinary. The questionnaire consisted of questions with regards to innovation and interdisciplinary competences. For each question, there was a scale ranged from "disagree" to "agree" with the possibility to mark "do not know" for each question. In the interests of high response rate, the data was collected anonymously using the program "Surveymonkey" [10].

A link to the questionnaire was sent to the students at the beginning of the course and again after accomplishment of the course. After collection of the questionnaire data, the results were analysed.

3.1 Findings/results

In autumn 2016, 233 students were enrolled for the course and they were all invited to participate in the questionnaire. At the beginning of the course in autumn 2016, 184(79%) students filled out the questionnaire and after accomplishment of the last course 144(62%) students filled out the questionnaire. However only 182 and 175 students answered the questions regarding innovation and multidisciplinary, respectively in the first round and 137 and 132 students answered the questions regarding innovation and multidisciplinary, respectively in the second round.

There were three questions regarding innovation which the student had to answer and the questions were; “I know what innovation is”, “Innovation is important for an engineer“ and “I like to work with open problems”. *Fig. 2* show the results from the three questions from the first questionnaire at the beginning of the course and from the second questionnaire after accomplishment of the course - which can be compared.

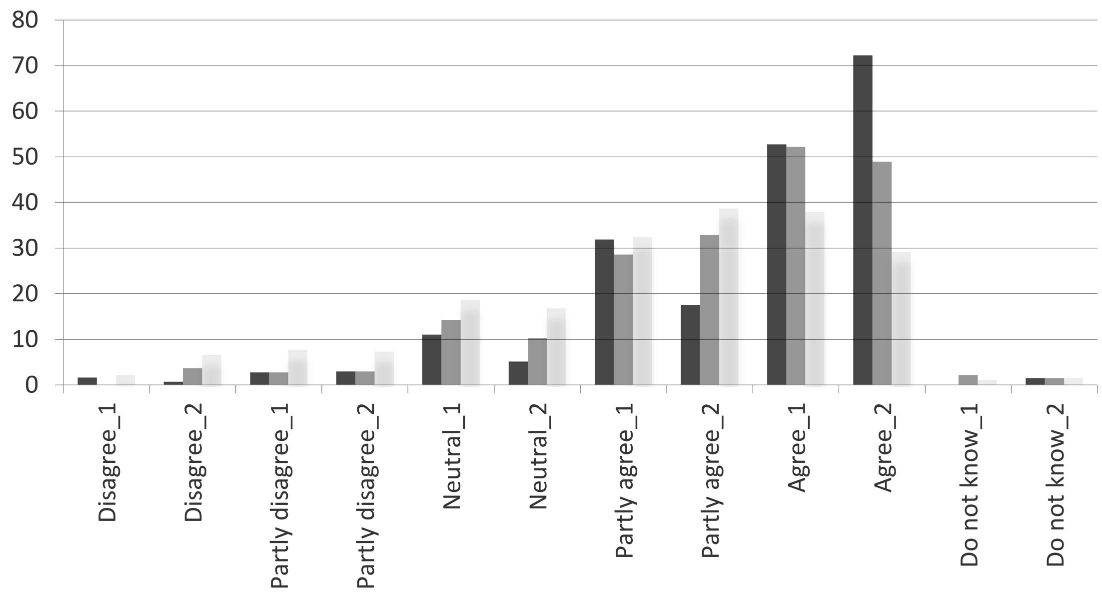

Fig. 2. Innovation: ‘I know what innovation is’ (Dark), ‘Innovation is important for an engineer’ (medium grey) and ‘I like to work with open problems’ (light grey). _1 represents the results from the questionnaire at the beginning of the course and _2 represent the results from the questionnaire after accomplishment of the course. Y axis is % of total number of answers.

With regards to innovation, more students agree that they know what innovation is and that innovation is important for an engineer after they have accomplished the course. However, there is tendency that there are more from agree to partly agree with regards to the question “I like to work with open problems”.

There were also three questions regarding multidisciplinary which the student had to answer. The questions were “I like to work with persons from my own education”, “I like to work with persons from other educations” and “I believe that multidisciplinary work is difficult”. *Fig. 3* show the results from the three questions from the first questionnaire at the beginning of the course and from the second questionnaire after accomplishment of the course - which can be compared.

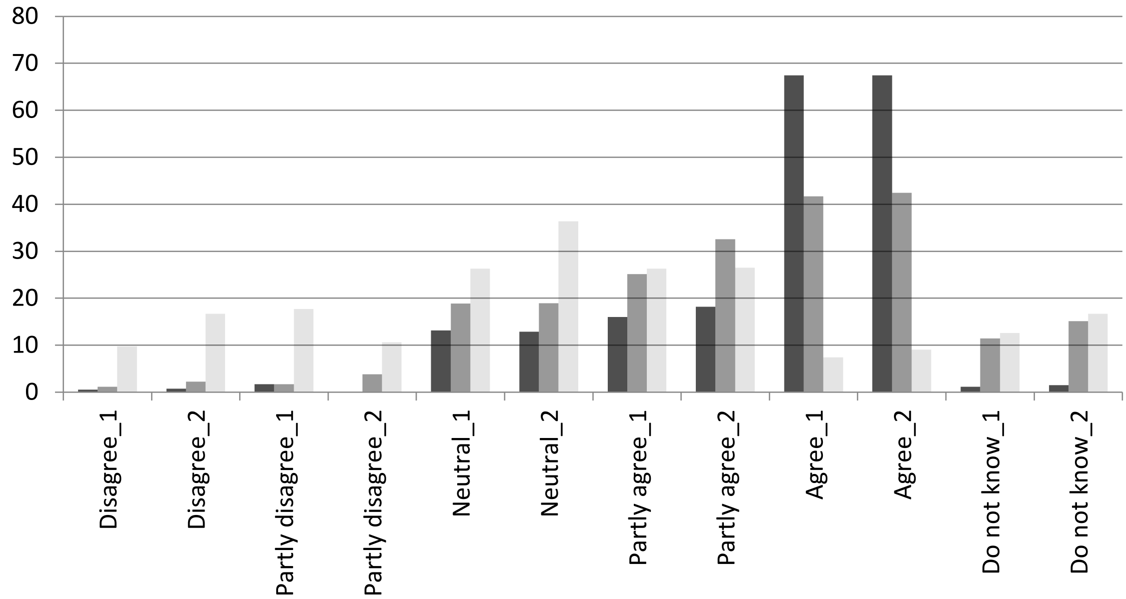

Fig.3. Multidisciplinary competences: “I like to work with persons from my own education” (dark), “I like to work with persons from other educations” (Medium grey), “I believe that interdisciplinary is difficult” (light) _1 represent the results from the questionnaire at the beginning of the course and _2 represent the results from the questionnaire after accomplishment of the course Y axis is % of total number of answers.

The results show that the students are becoming much more aware of what innovation is when they have finished the course. With regards to multidisciplinary, the picture is not so clear but a large part of the students believe it is difficult to work in multidisciplinary engineering teams after they have done it in innovation pilot. Our experience points to the observation (but no systematic investigation has yet been done in this area), that multidisciplinary is something the students in their study programs only have little experience with. The students ability to grasp the heterogeneity of the problems and their multidisciplinary facets, appear limited for the most parts. However, our expression is that many students really like to work with students from other programs and that they find it fun and motivating.

4 SUMMARY

Interdisciplinary innovation is important for the future engineers. In this paper, we have discussed how the Innovation Pilot-course defines a framework for collaboration between students from different engineering disciplines with aim of enhancing the innovation and multidisciplinary competences. The results from a questionnaire show that we have succeed in creating an understanding of what innovation is. However interdisciplinary is still difficult for the students to handle. In the future methods to learn and support student's interdisciplinary work need to be developed.

ABSTRACT

The readySTEMgo project is a collaboration between six European universities: KU Leuven (Belgium), Hamburg University of Technology (TUHH – Germany), University of Žilina (UniZa – Slovakia), Budapest University of Technology and Economics (BME – Hungary), University of Birmingham (UK), and Aalto University (Finland). The prime objective of the project is to identify students with an increased drop-out risk before the start or throughout the course of the first-year in STEM (Science, Technology, Engineering, and Mathematics) study programmes.

Before providing an overview of the most salient project findings, we will first address some key issues involved in identifying key entry requirements for first-year science and engineering students in a European framework. A number of institutional (e.g., university entry requirements & secondary school curricula) and diagnostic (e.g., available tests) elements complicate a uniform approach in a diverse European consortium. Against this background, we present the most essential key competences followed by a detailed overview of a number of interventions aimed at at-risk students in the different institutions.

Conference Key Areas: Engineering Education Research; Attractiveness of Engineering Education; Skills and Engineering Education

Keywords: Study skills; Achievement; Skills, University entry systems

INTRODUCTION

1 UNIVERSITY ENTRY: INSTITUTIONAL DIVERSITY

1.1 Open admission versus highly selective culture

In general, university entry can best be considered as a continuum between open-admission institutions (i.e., limited entry requirements) and highly selective institutions. We characterize the diversity in university entrance requirements based on three dimensions: (1) Minimal entry criteria; (2) Timing of application, and (3) First-year drop-out rate.

In the readySTEMgo consortium, three universities apply highly selective criteria, namely University of Birmingham (UK), BME (Hungary), and Aalto University (Finland). First, in all three universities, high performance standards based on a nationally organised matriculation exam scores (or the equivalent such as IB and similar) are set as pre-requisites for applicants to be eligible to apply. Additionally, at Aalto University applicants' score obtained in a nationally organised entrance exam in math and Physics/Chemistry are considered whereas grades obtained in secondary school are taken into account at BME. Both Aalto University and BME may also admit applicants based on achievements in high-ranking academic competitions, or exceptionally high scores in the matriculation examination [1]. Second, a common feature of all selective institutions is the early application deadline. Applicants need to select the programmes they are applying for in January-March prior to the start of the academic year (BME & Aalto) or even earlier (Birmingham). In the case of Aalto University, secondary school students spend the spring semester working both on matriculation examinations in March and preparing for the entrance examination for university in May. At the University of Birmingham, applicants are even given a full year to work towards the required A-level scores. By the end of the previous academic year, UK students submit their application. Those students of interest to the relevant department are made a conditional offer of a place based on their chosen A-levels. By May of the year of entry students in possession of more than two conditional offers select one university as their firm choice and one, usually requiring a lower set of grades, as insurance. A student who achieves the offer from his firm choice in August of the year of entry has his/her place confirmed. Altogether, secondary school students in highly selective contexts are expected to display higher levels of commitment and goal-orientation in working towards a specific target (see below). Third, drop-out rates are generally substantially lower after the first year in highly selective institutions. For example, at the University of Birmingham less than 5% drops out. Analogously, at BME drop-out ranges between 10-20% over the different engineering programmes.

Medium selective institutions are represented by TUHH (Germany) and UniZa (Slovakia). At UniZa, the final mathematics and physics grades obtained in secondary school and participation in the matriculation exams for these subjects are taken into consideration (since 2008, no STEM subjects are obligatory in the matriculation exam). Applicants who did not participate in the math and/or physics matriculation exam and do not meet the minimal criteria for admittance are obliged to participate in a selection interview on campus. In practice, almost all of these students are accepted because of normative funding [1]. Analogously, at TUHH (Germany) students need to successfully obtain their Abitur matriculation certificate. In theory, admission to TUHH is nominally based on the applicant's results in the matriculation examinations, with a special weight for grades in mathematics. However, due to the legal requirement to not deny admission to anyone as long as the maximum number of students has not been reached (and to the relatively lower interest in engineering careers compared to other fields), admission is not competitive. As a result of normative funding (UniZa) and obligatory admission legislation (TUHH), there is a high degree of diversity in beginning students' prior exposure to instruction and in their skills in science and mathematics. The decision-making and application process takes place at a later stage compared to highly selective institutions (after the matriculation exams) and drop-out rates are higher. For example, for some programmes at UniZa, drop-out rates after the first year can get as high as 50%.

KU Leuven (Belgium) is a university at the open-admission end of the spectrum. In Belgium, only minimal requirements apply for entering a science or engineering bachelor. Any student with a diploma of secondary education is allowed to enrol in any programme they want (except for medicine), regardless of their prior achievements or educational background. The secondary school diploma is not obtained on the basis of a nationally organised matriculation exam but exam grades at the end of secondary school. As a result, a large number of students subscribe for a science or engineering programme only one or two months before the start of the academic year at KU Leuven. For example, in 2015-2016, 30% of the students made their final decision during the summer holiday prior to the academic year. The proportion of students who drop out after the first year lies around 30%, a number that is fairly stable over the last years.

1.2 Consequence of different admission criteria

The aforementioned institutional diversity in terms of entry requirements has important consequences for the realisation of the objectives of the readySTEMgo project. A uniform approach focusing on STEM course content is highly impractical because of the heterogeneity in first-year student populations: highly selective universities select a population of high-achieving students whereas at more open-admission universities there is a wider range of achievement levels of incoming students. A single scientific measurement in full alignment with the different secondary school STEM curricula at the partner countries is not feasible.

Therefore, we did not focus on cognitive key skills such as prior knowledge in the fields of mathematics, physics, biology and chemistry. There is ample evidence for the importance of prior achievement levels in these fields for student achievement in higher education [2]. Instead, it was decided to shift the focus to more non-cognitive skills that (1) have the potential to be a predictor of study success, (2) offer concrete targets for improvement, and (3) can be measured through existing validated instruments. In the following two paragraphs we give an overview of our results.

2 KEY COMPETENCES: DUAL APPROACH

All partners agreed that, irrespective of the context, first-year students are confronted with large amounts of challenging course material. Students are expected to be architects of their own learning process and to make use of the resources available to them to master the required knowledge levels. As such, we decided to focus on (1) incoming student's learning/study strategies and attitudes towards learning (KU Leuven, TUHH, UniZa, BME, and University of Birmingham) and (2) levels of conceptual understanding in the field of mechanics, a central topic in most engineering programmes (TUHH and UniZa). At Aalto University, we mainly focused on the evaluation of interventions which are aimed to support integration of freshmen into student and academic communities.

2.1 Learning and study strategies

At the start of the academic years 2015-2016 and 2016-2017, the Learning And Study Strategies Inventory (LASSI, [3]) was presented to 7168 first-year students at KU Leuven, UniZa, BME, and the University or Birmingham. Except for the latter university, we were able to link these test results to student's obtained grades after the first semester at university. Our results show that students' self-regulatory skills levels (e.g., time management, concentration when studying, and motivation/persistence) were all significantly related to student achievement. Fig. 1 presents the results for the time management scale. In all three universities there was a positive relationship between better time management skills and student achievement (expressed as the proportion of ECTS credits obtained) in the exams in January: students with poor time management skills obtain significantly less credits compared to students with better time management skills. Similar patterns were observed for the other self-regulatory scales.

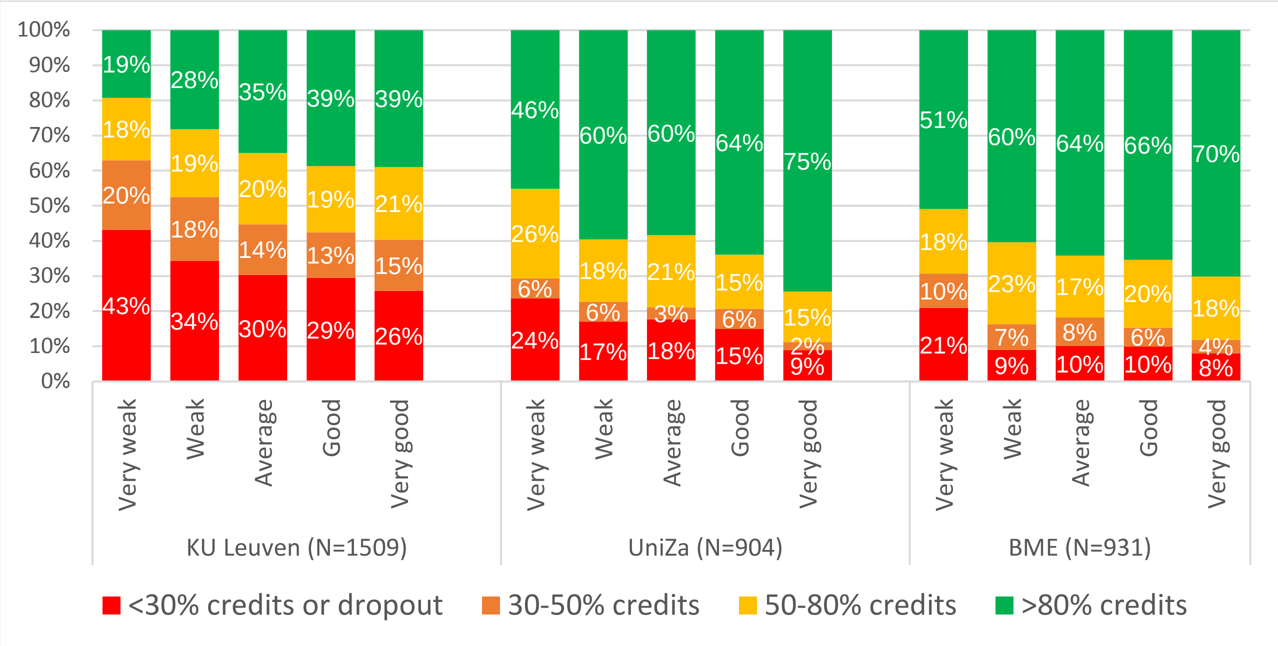

Fig. 1. Relationship between time management skills at the start and student achievement after the first examinations at university in 2016-2017 (KU Leuven, UniZa, and BME).

In sum, engineering students' self-regulatory skills levels at the start of university have important consequences for their achievement later on. Measuring the levels of self-regulating skills of incoming students may enable identification of students with an increased propensity to underperform or to drop out of the programme. Although this relation is supported in both open-admission (KU Leuven) and highly selective institutions (BME), this particularly applies for students from universities with a semi selective or open-admission culture since most of these students have not previously been required to attain externally set high level standards. In contrast, challenging target scores set by highly selective institutions require high degrees of self-regulation in the last stage of secondary school towards the matriculation exams. In order to illustrate this claim, the self-reported effort levels of students in secondary school in Belgium (KU Leuven) and the UK (Birmingham) are compared (Fig. 2). More specifically, during the first week of the academic year, students were requested to rate the following item on a 5-point Likert type scale: *"I had to work hard for my obtained study results in secondary education"*. 61% of the first-year students at the University of Birmingham agreed with this statement whereas for KU Leuven, this is only 13%.

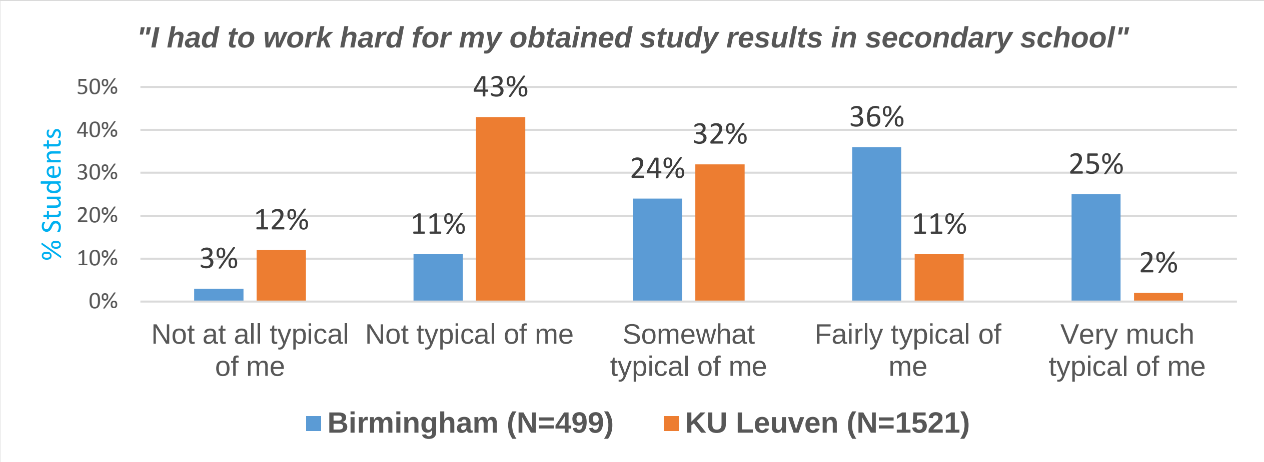

Fig. 2. Comparison of effort levels in secondary school in a highly selective (University of Birmingham) and an open-admission (KU Leuven) context.

2.2 Conceptual understanding

At TUHH and UniZa, a strong focus is on the conceptual understanding of students in the field of mechanics. It can be argued that students with a limited conceptual understanding at the start of an introductory Physics/Mechanics course are also at-risk. Both at UniZa and TUHH, rigorous pre and post test procedures (using the Force Concept Inventory and/or similar diagnostic tests), enable the determination of learning gains in terms of increased conceptual understanding after an introductory Physics/Mechanics course. Additionally, TUHH researchers examined the epistemological beliefs of first-year students about doing physics. For example, before the start of a large introductory mechanics course, 80% of the students indicated that they need to make sense out of formulas before they could use them correctly, and that they think it is useful to spent time on understanding where formulas are coming from.

In terms of learning gains in conceptual understanding, it was shown that interactive video teaching methods produced significantly higher learning gains compared to more traditional teaching methods.

3 INTERVENTIONS: A MULTIFACETED APPROACH

3.1 KU Leuven: Interactive student dashboard

At the start of the academic year 2016-2017, 1509 first-year students in the STEM field filled in the LASSI questionnaire regarding their learning and study behaviour in secondary school. Rather than only using the collected data for research purposes in the readySTEMgo project, it was decided to provide students with individual feedback on their personal scores on each scale. With the help of the researchers of the STELA project (www.stela-project.eu), an interactive feedback dashboard was developed with a central focus on actionable feedback (i.e., feedback that provides students with very concrete targets for improvement, [4]). The prime objective of this dashboard is to unveil information to first-year students on their personal self-regulatory skills (i.e., Concentration, Time management, Motivation/persistence, Anxiety, and Test strategies) and to stimulate a self-reflective process on their own learning behaviour. In order to avoid complex statistical interpretations, the dashboard uses simple visualizations complemented with textual explanations and concrete tips for improvement. 1406 students with a complete profile received an invitation by mail to consult their individual scores in the middle of the first semester. Altogether, 1135 (80.7%) of the students clicked on the link in the invitation email and entered the dashboard. 81.2% of the students that did click through, did so within three days. The proportions of students who consulted the improvement tips ranged between 15.2% (Performance anxiety) and 35.2% (Concentration). Additionally, the researchers found that students with a lower score on the five scales display higher levels of interaction with the platform (e.g., going back to an earlier page/tab, click on the improvement tips,…). For example, students with higher levels of performance anxiety consulted the improvement tips significantly more frequently compared to less anxious students.

3.2 UniZa: Physics summer course

In the framework of the readySTEMgo project, a summer course in physics was organised for the first time at Uniza. In this first edition, 87 students participated. In order to evaluate the effectiveness of the summer course, three evaluation criteria were put forward: (1) increased conceptual understanding of basic Newtonian Physics; (2) self-perceived usefulness in the short run; and (3) self-perceived usefulness in the long run (i.e., after the first semester). Of the 87 participants, 36 students participated in both the FCI pre and posttest. Statistical differences between the pre ($M=27.41$, $SD=10.69$) and posttest ($M=42.04$, $SD=12.27$) scores were tested using a t-test. The results clearly show a significantly higher post-test score after participating in the summer course $t\ (35)=9.76$, $p<0.001$. These results suggest that the summer course contributes to students' understanding of Newtonian physics. Second, in general, students reported high satisfaction levels with the summer course. On a 5-point Likert type scale, participating students consider the summer course to be very important ($M = 4.4$, $SD=0.81$) and useful ($M = 4.5$, $SD=0.55$). Even after the first semester Physics course, 78% of the respondents considered the summer course to be (very) useful and 69% of the respondents indicated that they were better able to check their prior physics knowledge.

3.3 TUHH: Tutorials & interactive teaching methods

Tutorials are defined as collaborative group activities that focus on instructional materials to target common misconceptions. In these tutorial sessions, a qualitative approach to problem solving is stimulated by trained assistants who guide a group of 20-25 students through the learning process by asking a number of specific questions. Evaluation of Tutorial instruction had begun prior to the start of the readySTEMgo project by collecting data on the level of expertise in the field of mechanics among incoming students. Through subsequent testing at the end of a first-semester Statics course, the effect of instruction with and without the use of Tutorials (for equal amounts of contact time) could be measured and compared. As the diagram of post-test versus pre-test scores from multiple years of instruction indicates, there is a statistically significant and practically relevant improvement of post-test scores for students of all levels of prior knowledge.

3.4 Aalto University: ABC-introduction week and student guilds

Prior to the start of the academic year, students at Aalto University are obliged to take part in a one-week intensive introduction course, which is later followed up by other supporting courses, such as the Academic Learning Community studies. Rather than focusing on the transfer of academic course content, the prime objective of this introduction week is to coach incoming students to adopt valuable learning and study strategies. Additionally, students are introduced to the student guilds and to their mentors at university. In the readySTEMgo project, we evaluated the self-perceived usefulness of the introduction week after two semesters at university. 46 out of 146 first-year students at the CHEM school filled in an online survey regarding the ABC introduction week and the student guilds.

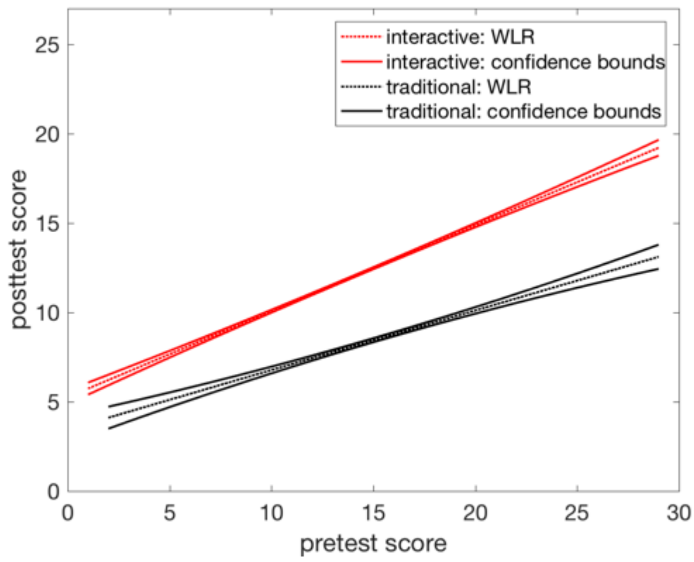

Fig. 3. Comparison of conceptual learning gains between interactive teaching methods (with tutorials) and traditional teaching methods at TUHH.

Altogether, 46% of the respondents agreed that the ABC-introduction week helped to them plan their studies. Only 13% of the students indicated that the ABC-introduction week has helped them to identify their strengths and weaknesses as a student. Peer support by the student guild showed to be an important resource for first-year students: 67% of the respondents indicated that the student guilds helped them to deal with school related pressure. Overall, it is evident that the peer support through social activities arranged by the guild, the mentoring system run by the guild and the extension into non-academic issues in student lives, identifies the student guild as a key element for student well-being. This has a clear positive effect on student attitudes towards tackling academic challenges.

3.5 BME: Math diagnostic test and bridging courses after enrolment

Since 2010, an obligatory math diagnostic test (‘*math zero test*’) at the start of the first semester (after enrolment), was introduced at BME. The need for the diagnostic test as part of the course requirements in first semester mathematics was generated by the current inconsistencies of the admission system of the Hungarian higher education, namely the weak correlation between admission points and diagnostic test scores [5].

Despite the high entrance score, many first-year students fail the math zero test. In the academic year 2016-2017, results of the readySTEMgo project showed that 23% of the students who failed the math zero test (N=380) obtained less than 50% of their credits after the exams in January 2017. For students who passed the math zero test (N=358), this number decreased to 8%. These results show that, even after a rigorous selection process, an obligatory math diagnostic test has added value in identifying at-risk students.

In order to support at-risk students in the transition to higher education, bridging courses in mathematics were introduced at all faculties. At the Faculty of Chemical Technology and Biotechnology, mandatory bridging courses in physics and chemistry (2 ECTS credits) were organised in addition to the bridging math course. Before the introduction of the bridging math course, more than 30% of the first-year students failed the “Mathematics 1” course. As a result of the participation in the bridging math course, the number of students who did not pass dropped drastically (below 20%). The effectiveness of both the bridging chemistry and physics course is similar: the failure rate dropped from about 50% to 25%.

4 SUMMARY

An important challenge for an international research consortium is the strict privacy legislation in some universities. In some cases, researchers are unable to gather data where student identity numbers would be matched with students grades through the official records (for example, Aalto University, University of Birmingham & TUHH). At the latter university, researchers administered an experimental approach with self-generated ID's in order to ask students directly for their self-reported grades (rather than access these data directly from the university records). Aalto University requires that use of data must be specified for a particular purpose, written consent is required, and data must be in a format that cannot be traced back to the individual. This is a challenge for studies which aim to follow progress of an individual student. Moreover, Aalto University collects an abundance of information at regular intervals for internal and external use. An attempt was made to collect data at Aalto for the present study, but the response of students in a highly complicated privacy setting in the present study, produced a very low response rate. As a consequence of these privacy regulations, we were not able to link the measured skills with students' actual performance in each university.

The common goal for all the partner universities is to deliver the best scientist and engineers by providing a study environment that (1) optimally supports the development of STEM skills and (2) engages into learning outcomes that lead to high employment of future graduates. On the other hand, even in the post-Bologna era, the readySTEMgo project has revealed that there are very divergent models and approaches for achieving learning outcomes in universities with very different institutional contexts. Each institution deals with its own challenges in a number of ways, ranging from a well-organised mentoring and guild system, an individual feedback system on learning strategies, interactive teaching methods, or STEM bridging courses. A thorough understanding of this diversity provided a number of interesting learning opportunities for all participating partners and helped to understand why successful educational recipes of one educational context cannot be univocally transferred to another.

ABSTRACT

Connecting the world sounds like a very challenging undertaking when it comes to gathering information, analysing and distributing data. *Internet of Things* is the concept of connecting any device to the internet while internetworking with devices. Possibilities for applications of *Internet of Things* are numerous to connect multiple systems while using the shared data for industrial and economic purposes or for empowering citizens and communities, among others. At Eindhoven University of Technology (the Netherlands) there are courses that aim at educating engineers to use applications for industrial purposes, but also for society and business solutions. The second year design-based learning sophomore course *Internet of Things* focuses on teaching students to solve open-ended problems both in industry or in hospital settings. . In this paper, we present the set-up of the *Internet of Things* project in which students explore different indoor localization scenarios. We explain as well the rational for the selected approach to teach this *Internet of Things* project. In addition, we give an overview of the main characteristics which feature the project, and we describe some expected benefits for the students.

Conference Key Areas: Curriculum Development; Skills and Engineering Education; Continuing Engineering Education and Lifelong Learning

INTRODUCTION

Imaging a connected world is easy although the potential of the *Internet of things* (IoT) application is still to discover. Possibilities for applications are manifold to connect multiple systems while using the shared data for industrial and economic purposes or for empowering citizens and communities, among others. IoT is more than just a buzzer word that can be applied to a wide range of devices, technologies and situations. IoT is the concept of connecting any device to the internet while internetworking with, for instance, cellphones, connected vehicles, wearable devices or buildings by the use of sensors, actuators, and software of network connections [1].

At the Electrical Engineering (EE) department at the Eindhoven University of Technology (TU/e) the theme of IoT is starting to boom up. The rationale to integrate IoT in the EE curriculum is driven by the fact that IoT is quickly gaining an industrial foothold in the Netherlands and internationally. In addition, engineers with IoT knowledge and skills are already required by many companies. Furthermore, while a need for this expertise is evident, there are no hands-on specific courses or lab environments at the tU/e where students can be exposed to the IoT experience. The motivation for this project is to develop an IoT hands-on project within the EE curriculum in order to facilitate students gaining practical skills.

In this paper, we give first an overview of the IoT project assignment within the EE study program. Secondly, we also provide an outline of the multidisciplinary components of this project to develop new insights into possible business applications. Finally, we address the expected benefits of this pilot project.

1 THE CONTEXT OF *INTERNET OF THINGS*

1.1 The rationale for the development of a IoT project in *FLUX*

Internet of Things (IoT) is the internetworking of physical devices, vehicles, buildings and other items. IoT enable devices including electronics, software, sensors, actuators, and network connectivity modules in order to collect and exchange data. IoT is becoming a growing market making a stand in the industrial world in the Netherlands and internationally.

At the TU/e (the Netherlands) there are courses at the Computer Science and Industrial Engineering departments devoted to teach students the technological aspects of IoT, i.e., architectures, device classes, protocols, application patterns and application examples, among others. In addition, courses also focus on developing business models and business cases on the products students make. However, the industry needs engineers with hands-on skills able to innovate and implement applications to match customer value needs and businesses.

The second year design-based learning sophomore project course *Internet of Things* at the Electrical Engineering (EE) department aims at teaching students to learn to use the applications of IoT around gravel**/**net, the expandable wireless IoT network of 50 nodes deployed inside of the EE department, the ultra-modern and recently-constructed building *'FLUX'* (See Figure 1). Moreover, our purpose for the development of this hands-on project is to make possible to run new applications, hosting various sensors and other hardware. This network is the result of several past and ongoing research programs. However it is not yet big and mature enough to be used for educational purposes. It should scale, in principal, to 180-200 nodes and become robust and easy to use allowing both teachers and students to focus on learning objectives rather than on solving technical issues.

Within this project, students learn how to design wireless links (including basic concepts of antenna design), and to optimize end-to-end latency over an IoT network. Likewise, students become familiar with different wireless protocols while exploring the relation between signal noise ration and channel capacity, the design of low energy systems by the use of algorithms of localization.

The project has a multidisciplinary character as elements of architectures from the computer science field and the economic values from the business world are integrated in the cases of the students to complement the electrical engineering knowledge that students will gain throughout the implementation. In addition, students from other departments, mainly Computer Science and Innovation Sciences, work together with Electrical Engineering in teams.

1.2 The description of the IoT project and the use cases

The end purpose of the IoT project assignment is to have students to solve open-ended and realistic use cases as they would be tackling complex problems of a real world scenarios. The assignment is based on tracing people in a factory, or patients in a hospital, or expensive equipment in the university. All assignments have a common denominator, i.e. indoor localization functionality. However, each of these cases has different requirements. On the one hand, in an industrial floor with robots and humans, safety critical situations picked by sensors have to immediately be notified to the control room or robots in the vicinity. On the other hand, patients in a hospital need to be tracked either in a waiting room or through the thick walls of a surgery room. The students are challenged to select a scenario in which both a tracking system as well as designing a solution for it is needed.

Given a selected scenario (i.e. industrial floor or hospital setting) the students need to define the functional and non-functional requirements in order to prioritize them together with the stakeholders and product owners. The sort-listing of these requirements will guide the student to the design of the architecture and the integration of the different technologies at market level. That is why the students will hold several presentations to fine tune the prototypes according to the market demands. The stakeholders and product owners will be present to these presentations in order to give their feedback as soon as possible, enabling students to readjust prototypes in iterations. It is therefore an evolving design trying to continuously address exactly the customer demands.

The system under design is split into both hardware and software components. Each human to be tracked should be equipped with a small low-power device. In reality, it is that device the whole IoT system is tracking; for clarity, we call this device mobile. The system consists of several fixed small devices deployed in various spots in a building (e.g. ceiling, walls, windows, floor, tables etc). Through different communication techniques the fixed devices “see” the mobile ones and through triangulation they are capable of determining their exact position. There are multitude dimensions to be considered when designing such a system. Accuracy of localization, number of fixed devices, data collection for centralized management, and lifetime of battery powered devices to name a few. These are questions inherent to the assignment of the students. Answering those questions, always in view of the priorities of stakeholders, will help the students short-list the wireless technologies (ultra-wide band or ultrasonic), the hardware (low-power or resource-full) and software architecture (centralized, hybrid, decentralized) to be used.

Together with this design process, the students will be integrating the chosen combination of technologies and will be testing their choices. It is via reading, trial-and-error and consulting with experts and stakeholders that they will be learning concluding to the best product design. The validation of their project output will be done on a real IoT testbed (i.e. gravel/net) deployed in the department of Electrical Engineering, at the TU/e. The testbed counts for 150 fixed devices and around 30 mobile ones. All the devices are extendible with the combination of technologies students will integrate. The testbed is able to collect monitoring information and let the student download performance data of their experiments. Yet, it is up to the students to design their experiments and applications running on top. An illustration of gravel/net is given in Fig. 1, 2, and 3[2]. For instance, in safety critical use cases (factory) gravel/net will be able to inform the students of the delay of an alarm trigger from sensors in the field all the way to the control room of the factory. Symmetrically, gravel/net will notify the students when a human stopped being traceable either because left e.g. the hospital or got in a surgery room. It is up to the students to assess whether that was a desired performance or reaction to an event.

Fig. 1

Fig. 2

[2] All images in figures 1–5 belong to the author George Exarchakos (g.exarchakos@tue.nl)

Fig. 3

Moreover, for industrial applications with coordination with robots, these have to be coordinated precisely one product to the other. When it goes about robots issues such as people and safety or alarm are key important elements. At the end of the course, the students will demonstrate that their solution can indeed solve the challenge taking into consideration specifications such as speed and efficient use of energy.

1.3 The IoT assignment

The objectives of this DBL IoT project are:

- To optimized wireless links (including basic concepts of antenna design)
- To optimize end-to-end latency over an IoT network
- To get familiar with different wireless protocols
- To create and analyse relations between signal noise ratio and channel capacity
- To design for low energy systems
- To apply algorithms of localization
- To conduct analysis of large data sets
- To develop new insights into possible business application of the IoT case

The motivation behind this project course is to introduce students in the world of the *Internet of Things* by applying technology, architecture and business models by tracing people and objects in indoor localization functionally assignments.

Next to the technical challenges also the business aspects of the project will be explored within the students' groups. Students make use of a business case and models to notify in the production line. The added element of including business models and cases is to have students to get involved in real live assignments in which they have to gather information on crowd sensing applications to be able to understand how crowd works, for instance, for safety and business purposes while deploying the necessary application. The key element is that students see the product development part of such as real-life case as they may work in a small company with similar challenges.

The structure of the project consists of seven weeks and eight contact hours per week in which students carry out the project activities. Besides an introductory meeting on the *Internet of Things* assignments, students get two support lectures on the two main multidisciplinary topics in this project, i.e. architectures, and business models and cases. These support lectures are given by lecturers from the Computer Science and Innovation Sciences departments. In addition, the Electrical Engineering lecturers are also involved in the direct supervision of the teachers.

Following the educational principles of problem-based and project-based learning, students work in teams together throughout seven weeks. The groups are guided by a supervisor or project leaders. These are older bachelor or master students with broad knowledge on the *Internet of Things* as they have been involved in the construction of the network. The groups are made out up to 6 students and the tasks are divided among them.

The follow-up of the project activities and interim products is based on mid-term presentations in which students report about the progress of the project, main obstacles but also the challenges ahead and how these will be solved. In these mid-term presentations the interim products and prototypes, are assessed. Students receive feedback from the experts on how to make improvements including from a company in charge of providing proof-of-concept input. The presentations and final report are assessed against quality of final products.

2 INSTRUCTIONAL DESIGN IN ENGINEERING EDUCATION

2.1 The Design-based learning approach of the *Internet of Things* project

Design-based learning (DBL) is an active learning teaching method similar to Problem-based learning [4] and Project-based learning [5] engaging students in solving real-life design problems while reflecting on the design and learning process [6]. DBL was introduced at the TU/e in 1997 as an educational approach for engineering education. The unique element of DBL is that it is grounded in the *process of inquiry and reasoning towards generating innovative artifacts, systems and solutions* [7]. DBL emphasizes the engineering design process resembling authentic engineering settings in which students make decisions during the design cognitive thinking processes as they go through iterations in generating specifications, making predictions, experiencing and creating solutions, testing and communicating [7].

Resembling the DBL model from empirical literature, we have included the features of DBL [8], i.e., *open-ended, hands-on, authentic* and *multidisciplinary* aspects in the instructional design of the *Internet of Things* second year bachelor project. The *open-ended* character of the project is featured by the fact that students get a general description of the cases to explore from different perspectives. As an instance, students are to trace people in buildings, workers in a factory, patients in a hospital or just lab equipment. Besides the description of the use case with incomplete information and some specifications expected in the final systems, students' teams are to experiment iteratively with different architectures to be able to choose the appropriate one that matches the technology selected for the design. Within this experiencing phase and following the common engineering design process, students make a thorough out analysis of the use cases and requirements and choose some criteria to select the proper architecture. In addition, students' teams analyse the business aspects and make priorities of the requirements and features of the system to be developed.

As in the engineering design cycle, students formulate own design plan, and seek for alternatives in the design of the architecture and integration of existing architectures and communication technologies. In the integration process, the selection and assembly of the required hardware, installation of software, modules and libraries, etc., should be included. The next steps in the design process are to test iteratively the prototypes and experiencing repeatedly various architectures in order to design a minimum viable product, i.e. a prototype which is not the final product. The design and testing phases should be in iterations so that students can expand the design with different features of each specific case. A relevant element within the design process is the feedback to support the construction of a viable product so that this can be sold and become profitable. These project assignments provide students the opportunity to experience a typical production development process from the organization of working from a traditional waterfall production and design work into a much more *Agile* type of work consisting of short iterations allowing companies to realise new products in short time.

The fact that the assignments are embedded in *real life* industry tasks make the cases more *authentic* resembling jobs students might get in companies. The teaching staff from the Computer Science and Industrial Engineering departments will be also providing feedback as part of the customers' roles they will be playing. Moreover, the *hands-on* component of this project is actually inserted in the generation of knowledge from each iteration in the design process which is afterwards applied in a new iteration producing new information on the prototype to make.

In this *hands-on* project students are asked to work in *multi-disciplinary* groups to address a challenge concerning how a large pool of IoT devices connected to form an intelligent network can be used to solve practical engineering problems relating to emerging applications such as autonomous driving and in building navigation and localization. The rationale for multidisciplinary lies in that students from the different three departments, i.e. Electrical Engineering, Computer Science, and Industrial Engineering will be working together and share expertise from multiple domains i.e. design, integration-implementation, testing-deployment and business models. As a matter of fact the involvement of Computer Science in this project is related to the software architectures of a system, of Electrical Engineering to the hardware assembly and of Industrial Engineering to the value proposition and the business models.

3 INNOVATION SPACE AND THE ENGINEERS FOR THE FUTURE

The *Internet of Things* project is a pilot which has potential to expand and link with the newly initiated concept of Innovation Space at the TU/e. Since 2016 the idea of the TU/e Innovation Space (still under construction) is built upon the rationale to have students work on hands-on engineering assignments in multidisciplinary teams while dealing with challenging and *complex societal and industrial challenges, create prototypes and develop innovations in collaboration with researchers, businesses and other stakeholders...*[2]. The added value of this initiative is the strong scientific collaboration that the TU/e has with the surrounding industry, with researchers and businesses.

The concept of Innovation Space does not stand alone in the world. Looking at other initiatives overseas, for instance, the Design Factory at the Finnish Aalto University, this has been an inspiring example to adjust that model into the TU/e pattern. The experience of *Design factory* illustrates and leads the TU/e project to make possible and give form to a space in which the physical and mental working environment for product developers and researchers come together to encourage and to enable fruitful interaction between students, researchers, and professional practitioners. Following the already 10-year old Finnish model, the TU/e innovation space provides a setting to inspire teaching staff and students for which lectures and workshops are organized. In addition, the fact that the Innovation Space provides a scenario for the implementation of multidisciplinary engineering projects encourages the engineering thinking of creating prototypes and transforming those into products, services for the society in order to stimulate businesses. Compared to other models, the TU/e innovation space specific character lies on encouraging the cross-fertilization between departments as well as the cooperation with the business community. The operationalization of such an ambitious undertaking is actually a step ahead in realizing the vision of the TU/e to educate the Engineers for the Future [3].

4 DISCUSSION

The *Internet of Things* project is a pilot project that has been developed to introduce students in the world of communication technology and to learn them the application of technology, architecture and business models by tracing people and objects through indoor localization functionally assignments. The added value of this project is that is a pioneering course within the Eindhoven University of Technology as it is devoted to promote *hands-on* application of a connected world rather than in a lecture-type course. The relevance of this project is therefore twofold: first of all, the IoT project is aiming at promoting practical applications of content; secondly, the project aims at integrating different disciplines as a realistic scenario of what the engineers for the future will be dealing with in the industry in order to stimulate multidisciplinary projects.

It becomes difficult at this stage to sharply identify the benefits and students' gains of this project as it is now in a pilot phase. We foresee however some advantages and effects for students. First of all, the rationale for this project is based on integrating continuous iterations in the design process emulating the *Agile* method. By doing so, we expect higher quality of product design, in terms of accuracy of localization, measurements of distance, or in the optimization levels of the wireless network, among other performance items of the devices. Furthermore, the fact that students can choose different scenarios and perspectives to approach the problem solution will require creativity to combine technologies and architectures. We expect therefore new eye openers in the models students will design. A thorough out evaluation of results after the implementation of this pilot project will allow us to analyse students' gains in this IoT project.

The future challenges of this project will be to include elements of value for money in the design review in order to fine-tune the assignments and students' products according to the clients. In order to embrace the value for money component it will be necessary to make the project sustainable and gain financial support to be able to buy sensors, actuators and missing parts upon which students will make choices based on the technology and architectures they are planning to use. The need to link with the industry and with Innovation Space university project becomes also relevant.

5 ACKNOWLEDGMENTS

We would like to thank the contribution of the teaching staff of the Computer Science department, prof. dr. J.J. Lukkien, and of the Industrial Engineering & Innovation Science, prof. dr. B. M. Sadowski from the Technical University of Eindhoven (TU/e).

ABSTRACT

The actual development of communication and new technologies allows improving the pedagogy methodologies. In this work a new teaching methodology which combine online resources via Small Online Private Course (SPOC) with collaborative learning techniques is presented. This new methodology has been implemented in the course "Elasticity and Strength of Materials" in the Bachelor´s Degree in Industrial Technologies Engineering. As a benchmark of the methodology, 250 students and 6 teachers have been involved in the experience. The results of the study show how it is possible to improve the academic results with respect to the traditional teaching methodologies, improving as well transversal competences.

Conference Key Areas: Open and Online Engineering Education, Engineering Education Research, I want to contribute to solve local problems

Keywords: Learning design, Learning mark, Motivation, SPOC

INTRODUCTION

The technological development during the last decades, allows the teachers to employ new techniques based on online resources, adding value to the traditional teaching methodologies. Leading examples of this development are blended-learning (Bourne et al. 1996) and flipped-classroom (Kim et al. 2014). One of the main advances in these methodologies is the availability of moving part of the contents of the course to online resources, releasing time to apply other technologies in the classroom. The experiences during the last decades prove the improvements in engineering bachelors of collaborative learning, community learning and learning based on examples or projects (Smith et al. 2005).

Several studies show the improvements in the learning process of applying these new methodologies: Mendez and González (2011) balance the workload of each student based on its activity and its results using fuzzy logic techniques in a Control System course. The main conclusion of this work is the identification of the motivation as a driven parameter for the academic success. In other words, the use of online learning methodologies not only eases the learning process but also increases the student motivation.

Yigit et al. (2013) proved that the mark results of the students in a coding subject are similar between traditional teaching and blended-learning methodologies. Using flipped-classroom in 3 different courses of engineering, humanities and social studies, Kim et al (2014) allowed identifying the main standards or principles for all courses.

Blaeper et al. (2014) studied the effect of the reduction of the on-site time in the classroom (2/3 of the total) for online contents in a physics course. Moreover the class was moved to an active learning classroom. The student's knowledges of the subject were improved with respect to the traditional method. At the same time, the perception of the students about the course has been upgraded. Proving the efficiency of the active learning classrooms, although the number of students in a collaborative classroom is lower than in a traditional classroom, the achievements are greater, reducing the total time of learning process.

One of the disadvantages of the online contents is its dependence to the spreading of the internet access in the country. Banday et al. (2014) studied this effect in developing countries where the internet access is lower than in the occidental ones, and proposed tools to reduce the effect of these disadvantages.

The emerging of new technologies allows the teacher to apply innovative techniques in the teaching process, making the study time become a game. Bodnar et al (2016) presented a review of the gamification of different courses in engineering proving that this technique increases the motivation and improves the learning process.

This work presents the implementation of a flipped-classroom methodology in the course "*Elasticity and Strength of Materials*" in the Bachelor Degree in Industrial Technologies Engineering during the course 2015/16 at the University Carlos III of Madrid. The theoretical sessions were moved to a Small Private Online Course (SPOC) and the time released was used for a collaborative learning technique. The results of the final exam show that the new methodology could improve the students' academic results and simplify the learning process.

1 TEACHING METHODOLOGY

The teaching methodology designed should fulfil the criteria of the European Higher Education Area (EHEA) applied in Spanish universities. Moreover, it should be done in the actual classrooms, timetable and groups of the Bachelor Degree in Industrial Technologies Engineering at the University Carlos III of Madrid

Each group of this engineering bachelor has 2 sessions of 2 hours per week, the first one (Aggregated group) with a maximum of 120 students and the second one is a reduced group of 40 students. Usually the Aggregated group is used to explain theoretical contents and the reduced sessions are employed to solve practical exercises. Subsequently the students should study the theory and then try to solve the problems by its own. The number of students per year is around 250, which are divided into 3 aggregated groups and 7 reduced groups.

The implemented methodology is based on the idea of flipped-class-room, because some of the common tasks done by the students in the classroom in the traditional methodology, are moved to homework and vice versa. The learning process is as can be seen in Figure 1:

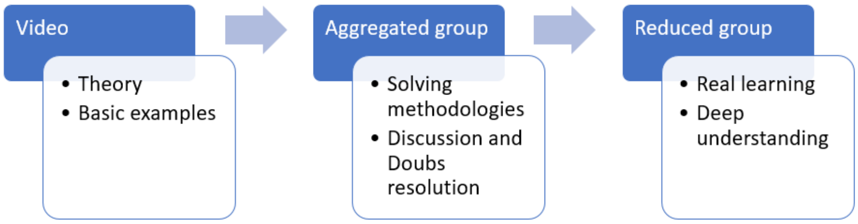

Figure 1. Learning process implemented in the course

- Theory contents are recorded in videos and uploaded into the SPOC platform. These videos should be attended/viewed as homework before the class in the aggregate group. Therefore the students, instead of listening the teacher in the classroom, view the video and hence they can decide the time and rhythm of the explanation and even repeat selected parts. Moreover the contents are multiplatform accessible, so the students decide the way to access to the information
- The aggregate group sessions are used now for discussing the theory in a more active way, from the students' point of view. Moreover different problems are solved and discussed, moving the task done in the traditional methodology of the reduce group to the aggregate one. The bigger number of students enriches the discussion and the possible doubts of the theory.
- Finally, the reduced groups are re-designed to accomplish a collaborative learning process. The group of 40 students was divided in groups of 5. Each odd week the group of 5 should solve by its own a problem, discussing the doubts with the teacher. The even weeks the groups present and explain the solutions to the other students, each team member should present at least 1 time the solutions and answer the doubts of the other students and the teacher's questions.

2 EVALUATION STRATEGY

The traditional way of marking consists of 60 % the final exam mark (4 different problems) and the 40% of the course mark correspond to continuum assessment. This continuum assessment was composed by a 15% the laboratory marks and 25 % the partial exams. Moreover it is required at least 4.5/10 in the final exam to pass the course.

The new evaluation strategy conserves the old weight between the final exam and the continuum assessment but, in this case, the 25% corresponding to the partial exams were assigned to the marks corresponding to the teamwork evaluation: 1/3 of this mark corresponds to the solving evaluation of the team (equally for all the team members), 1/3 corresponds to the evaluation of the presentation, and the rest (1/3) is the mark of the answers to the teacher questions after the problem presentation.

3 SPOC ENROLMENT

Most students attend the SPOC course. The SPOC contents are videos, self-assessment exercises and evaluation problems. After each video, the students should answer a series of questions designed to test the understanding of the concepts explained in the video, these exercises or questions are not taken into account for the final assessment. The evaluation exams consist on 6 questions or problems at the end of each week. The entire course was divided in 13 weeks and the final mark is the average of the marks of the 13 week's evaluation tests. Based on the results of these weekly tests, 83% of the students pass the SPOC course, 90 % of these obtain a mark bigger than 7/10 (mark grade B or A). Only 17% of the students did not pass the SPOC course, and 70% of this percentage gave up the SPOC course, hence they did not answer the tests. These results are considered positive, due to the fact that in all the courses there is a percentage of the students that give up the course without attending the final exam. This percentage (19%) was similar to the one of giving up the SPOC course.

4 RESULTS

The results of this work are compared with respect to the marks of the year 2014/15 and 2015/16 in the ordinary final exam of the course "*Elasticity and Strength of materials*". Besides the target population are different, the number of students involved is large enough to be considered as equally dispersed, 269 students in 2014/15 and 287 students in 2015/16. Moreover, the mean academic grading of both groups during the bachelor courses were similar. The mean academic grading of the student in 2014/15 was 6.19/10 and the grading of the students in 2015/16 was 6.05/10.

Table 1 shows the percentages of the total number of students that have passed the course, the percentage of students which pass the final exam, and the percentage of the students that have failed the exam (obtaining a mark greater than 4.5) but pass the course due to the continuum assessment mark. These results show that the percentage of the students who pass the course increase a 40% in relative terms, but the number of students with a mark greater than 5/10 in the final exam was increased in 78%. This means that a great number of students in 2014/15 did not pass the exam, but pass the course due to the continuum assessment mark.

	2014/15	2015/16	Differences
% Students pass course	47.21%	66.55%	41.0%
% Final exam positive	31.60%	56.45%	78.6%
% Students which pass the course due to the continuum, assessment.	15.61%	10.10%	-35.3%

Table 1. Percentage of students that pass the course in comparison with 2014/15

Table 2 shows the marks obtained by the students in the final exam for both 2014/15 and 2015/16 academic years. The number of students that give up the course decreased, which means that the number of students that considered that they were prepared for the exam increased. The percentage of students that did not pass the course decreased to a half in comparison with the previous year, and the percentage of passed increased. The more remarkable result is that only 3% of the students in 2014/15 obtained a B mark (7/10) and none of them an A mark (9/10). However, with the new methodology, 17% of the students obtained a B mark (7/10) and 6 % obtained an A mark (9/10). These results show that the knowledge acquired by the students can be considered remarkably better and it is translated into the marks of the students.

	2014/15	2015/16	Differences

Give up the course	23.79%	18.82%	-20.9%
Failed	44.61%	24.74%	-44.5%
Pass	28.62%	32.75%	14.4%
B mark	2.97%	17.07%	474.1%
A mark	0.00%	6.62%	
Total pass	31.60%	56.45%	78.6%

Table 1. Final exam marks distributions

Figure 2 depicts the distribution of the marks of the exam in the years 2014/15 and 2015/16, showing a normal distribution. In 2014/115 the normal distribution was centred in a mean value of 4.7 and a standard deviation of 1.39. Therefore the students did not pass the exam but passed the course due to the continuum assessment mark. The results due to the presented methodology, course 2015/16, shows a normal distribution centred in 5.89 with a standard deviation of 1.84. Most of the students passed the exam, and the number of marks higher than B increased.

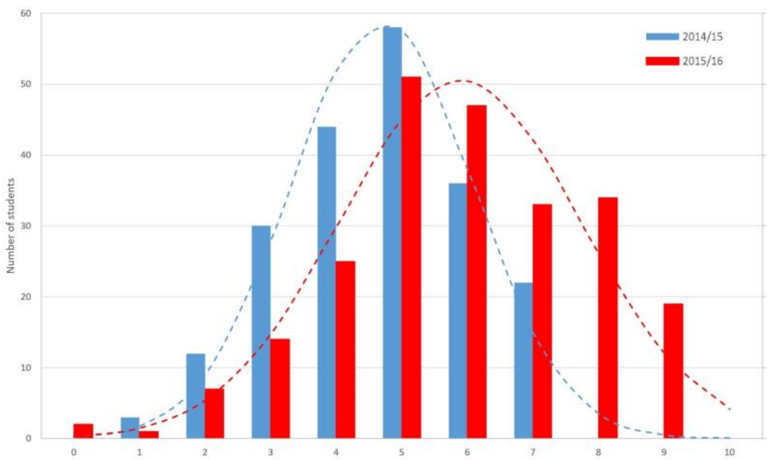

Fig. 1. Final exam mark distribution 2014/15 and 2015/16.

5 LEVEL OF COURSE SATISFACTION

The students from the University Carlos III of Madrid answer a satisfaction poll about the teaching methodology for every course and year. This poll has been used to evaluate the presented teaching methodology. It is important to remark that the students answer the poll before the final exam, so the answers are independent of the increased mean mark in the final exam. The course has 6 teachers in 3 aggregated groups and 7 reduced groups. Only 1 teacher was different between the 2014/15 and 2015/16 courses; that change affected only to the 30% of the students. The mean results of satisfaction of the students in 2014/15 was 3.51/5 whereas in 2015/16 was 3.6/5. There is a slightly rise in the satisfaction, but not significant to be considered. The significant change in the poll results was in the poll`s comments. In 2014/15 the students' comments or complaints were in the way of:

- The students considered that the number of problems were scarce

- The course syllabus is huge and each division is taught summarily
- The theory sessions are difficult
- The theory sessions are useless

In 2015/16 the comments or complaints of the students, can be classified also in:

- The students required more theory concepts in the on-site sessions
- There are weeks with partial exams of other subject that reduced the available time for the SPOC
- The students requested partial exams
- The presentations of the other students, explaining the problem resolutions are useless

The similar values of satisfaction in both years conclude that the new methodology has been similarly accepted by the students. Moreover there are different student profiles and some has better acceptance under new methodologies. In the traditional methodology, there is a group of students requesting more exercises, with the new methodology a new group appear requiring more theory weight in the on-site sessions, similar to the traditional method. The new method forces the student to learn out of his comfort zone, they are used to a passive learning in which listening to the teacher is the main task. In the new methodology they should study and prepare the subject by their own. The new method pushes the student to collaborate in team works and explain his results to the group by a public appearance, which usually turns out in complaints.

6 CONCLUSIONS

It can be considered the success of the new method, due to its results in comparison with the traditional methodology. Although a deeper analysis, including more polls and a bigger population is required to identify the aspects that causes the success, even so it can be identify possible success parameters of this experience:

- The blank sheet of paper magic: the most important time in the learning process is the one in which the students try to solve a problem by their own. Although the method assures that the teacher joins the students in this experience and serves as guidance.
- The relationship student-professor. The methodology implies a closer relation, which confers more confidence and reduces the expert syndrome in the teacher understanding the student point of view. This experience not only improves the learning process, but also gives to the teacher the opportunity of enhancing his explanations in the weaker knowledges points of the students.
- The spreading of enthusiasm. The effort and passion of the teacher is spread or transmitted to the students, and his answers to the teachers are an “extra” effort, trying to keep up with the professors.
- The task of every week homework. The demanding task of SPOC videos prevents to quit the course and enable a better understanding of every lesson. The success of the results is due to the fact that the students have worked more and better, because a better guidance in the learning process.
- The student behaviour depends on the environment. The traditional method used during decades, teaching by a passive listening, does not prepare the students for the professional career, where should be active and collaborative. This new methodology gives the principal role of the learning to the students.

- The new methodology is not only a success in the subject taught, but also increases transversal knowledges e.g. “the capacity to communicate its knowledge in public appearance” and “team working”

Employability and the knowledge, skills and competencies of engineering graduates
Case Study of Finnish Engineering Education

ABSTRACT

This system paper will examine the amount and quality of work experience of newly graduated Finnish professionals from the field of technology and the knowledge, skills and competencies that the graduates have gained through formal engineering studies and through work experience gained during studies.

In the future world of work the ability to adopt and to apply new knowledge are crucial skills and enable life-long learning. New learning models such as problem-based learning, project-based learning, co-ops and CDIO are needed in providing engineers with skills and competencies they can utilize throughout their career. As the graduates have a significant amount of work experience it allows the universities to utilize the work experience and to recognize the competencies the students have gained outside the classroom.

Conference Key Areas: Skills and Engineering Education

Keywords: employability, work experience, graduates, skills

1 INTRODUCTION

Academic Engineers and Architects in Finland - TEK is a service and labour market organization for professionals and students in the area of engineering and technology. The 73 000 members of TEK mostly hold a M.Sc. degree in engineering, technology, architecture or natural sciences. In addition to labour market issues, TEK actively participates in the developing engineering education and further professional development. TEK works in close collaboration with universities, political authorities, representatives of working life and other relevant stakeholders. One of the main interests for TEK is to make sure that the Finnish Universities of Engineering and Technology will have the best possible funding and framework to provide top quality engineering education.

One of the practical tools used for monitoring the quality of engineering education is Graduate Feedback Survey which is directed at newly graduated M.Sc. engineers and architects. TEK and the Finnish universities of higher engineering education have conducted this joint feedback survey on a national scale for graduates since 2011. The main purpose of the feedback survey is to gather comparable information on the quality of the Finnish engineering M.Sc. degrees. Some highlights of the areas the survey covers are the quality of formal studies, the skills, competencies and knowledge gained by the graduates and their employment after graduation. This graduate feedback survey covers over 95 per cent of the Finnish M.Sc. engineering graduates. In 2016 the response rate was as high as 68 %.

In Finnish higher education it is rather typical that students gain a significant amount of work experience in industry during their studies. On average a graduate in the field of engineering and technology has more than 2 years of work experience of which 8 months is study related and equivalent to graduates level of education. Typically also the master thesis is done in industry which means that graduates have a strong professional network already at the time of graduation and they have demonstrated the ability to apply theory into practice.

This paper will present some recent findings from the data regarding employability and the knowledge skills and competencies the students gain from their studies and the work experience they gain during their studies.

2 THE FINNISH HIGHER EDUCATION SYSTEM

2.1 The Finnish higher education system in the field of engineering and technology

Finnish higher education system is based on a dual/binary system of higher education. The higher education institutions constitute of universities and universities of applied sciences (UAS). The members of TEK include professionals with at least second cycle university level degrees and students currently studying for second cycle degrees. Seven out of fourteen Finnish universities provide studies in the field of engineering and technology.

Finnish higher education system is not governed by any strategic policy papers per se at the moment as the policy paper system of higher education is currently under reform. The latest of the strategic policy papers called *koulutuksen ja tutkimuksen* *kehityssuunnitelma KESU* (education and research development plan) covered the development of higher education up until 2016. Currently the strategic goals of higher education are defined only in the government programme of 2015-2019 with four main goals for higher education: enhancing student selection processes, year-round study possibilities, digital learning environments and reviewing the eligibility demands in public positions.

Finnish higher education policy has aimed for decreasing length of studies for more than a decade. Regarding statutory developments, university students used to have unlimited time to complete their studies which has been limited to seven years since 2006. The public funding of universities is also strongly governing to faster completion of studies with amount of students achieving degrees and at least 55 study credits per academic year being rewarded generously. The universities are also governed for decreasing study times through university-specific negotiations arranged every four years.

The government policies aiming for shorter study times are justified with the aim to increase the amount of time population is active in the labour market. The long study times of Finnish students however seems not to decrease the length of careers at least in the field of technology: the study times lengthen mostly because the students are very active in the labour market already during studies. The culture of working alongside studies is also very beneficial for the students as explored further in this paper.

2.2 Monitoring the output: Graduate Feedback Survey

The graduate feedback survey discussed in this paper is a joint effort of TEK and those Finnish universities which provide education in the field of engineering and technology. The survey has been conducted since 2011 and it covers over 95 % of all graduates from academic studies in the field of engineering and technology. The response rate of the survey is very high, for example in 2015 the response rate was as high as 72 % of all graduates and in 2016 the responserate was 68 %. The survey is yearly open from the beginning of January until the end of December. The survey is rather extensive with 56 overall questions and an estimated response time of 45 minutes.

2.3 Culture of working along studies in Finland

Gaining work experience while studying is very typical in Finnish higher education system and Finnish labour market. Working during studies serves many functions for the students. First of all, the financial aid provided for students by the government is in many cases not enough to cover living costs. Secondly working during studies is regarded as a great way of enhancing ones skills, competencies and knowledge. Third, work experience is highly valued in the Finnish labour market, even if the experience is not from the field of studies or does not match the level of education. Work experience from ones own field of science also provides valuable contacts and networks to possible future employers. (TEK opiskelijatutkimus 2016) The percentage of employed university level students are presented in Figure 1.

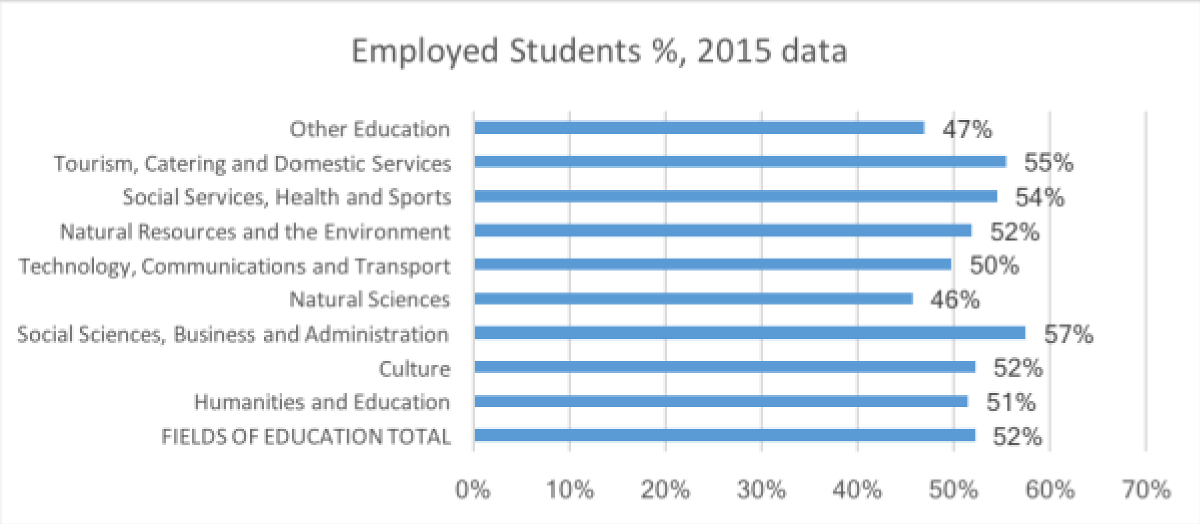

Fig. 1. Percentage of employed bachelor and master level students by field of education in 2015. (statistics Finland)

3 SKILLS, COMPETENCIES AND KNOWLEDGE GAINED IN STUDIES AND WORK EXPERIENCE

The skills, competencies and knowledge of Finnish graduates in the field of engineering and technology develop both through formal education and work experience gained during studies. The TEK Graduate Survey the development of 26 categorized skills, competencies and knowledge through both formal education and work experience. The results of the 2016 survey are illustrated in Fig. 2.

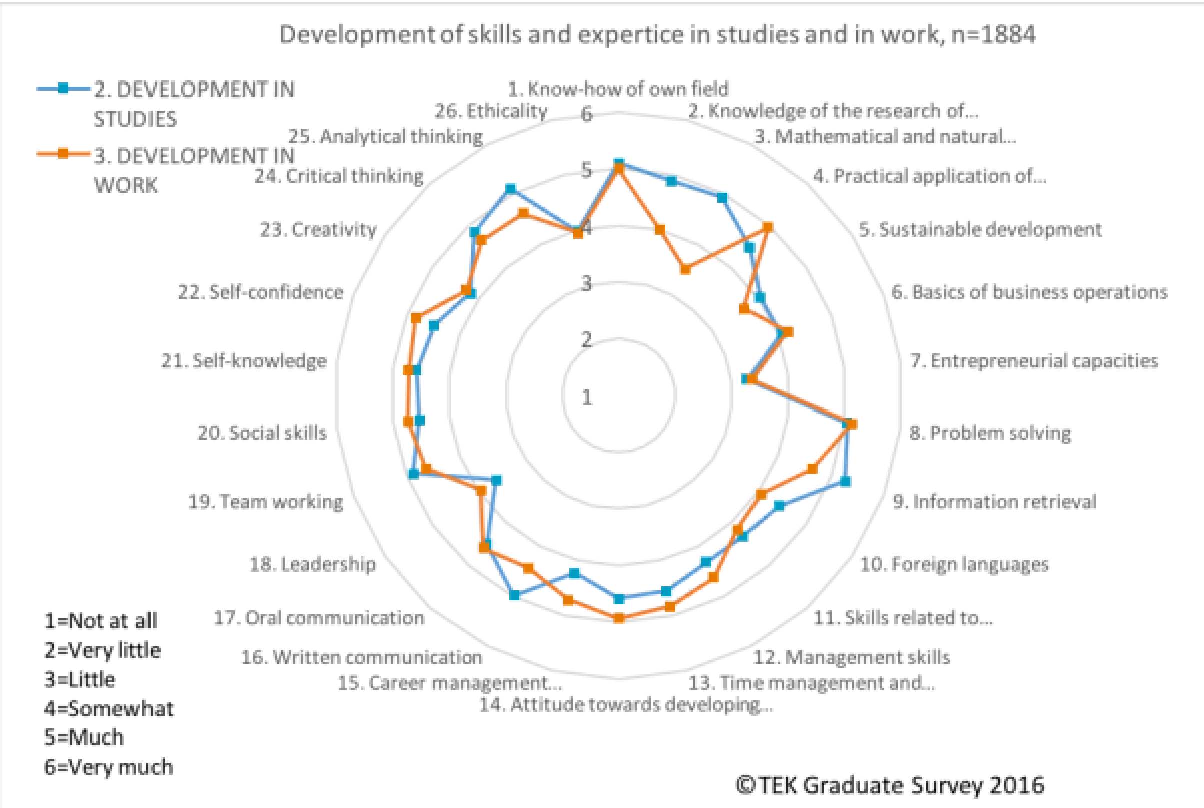

Fig. 2. Self-evaluated development of skills, competencies and knowledge of M.Sc. in

Tech graduates through formal education and work experience gained during studies in 2016. (TEK Graduate Survey 2016)

The differences in development of skills, competencies and knowledge however seem to emphasize the very hard to develop skills gained in formal education such as knowledge of research, mathematical and natural science skills, information retrieval skills and analytical thinking. Also the foundations for learning the skills are set out in formal education after which it is likely that further development of skills through work experience is easier.

While the differences of development the skills differ quite little between formal education and work experience, the differences highlight the importance of both factors in producing high-quality graduates in the field of technology. Many categories develop somewhat identically through both education and work experience but the differences are what matter the most. Formal education clearly lays the groundwork for further development by improving the core skills in the field of technology: mathematical and natural science skills, information retrieval and analytical thinking to highlight a few. Work experience also play a very important role by compensating where formal studies are fumbling: practical application of theories, attitude towards developing own skills and leadership skills to name a few.

4 EMPLOYABILITY OF GRADUATES

The Finnish M.Sc.'s in the field of technology gain on average over 2 years of work experience during their studies However, the total study time of the respondents is approximately seven years with the target total study time being five years. According to the TEK Graduate Survey, the studies are delayed due to many reasons such as lack of motivation and lack of support and guidance in thesis work and/or studies. However the most common reason for delay in studies is working while studying.

Working alongside of studies provides a wide range of advantages for the students as explained in chapter 1. In addition to what we covered in chapter 1, work experience is also a source of motivation for studying as students get a better perspective and understanding on what kind of a career they would like to pursue. Working while studying also helps choosing courses and whole majors or minors according to interests discovered through work experience. Another perk of working alongside studies is that higher education degrees include mandatory or optional traineeships for which students also get study credits for.

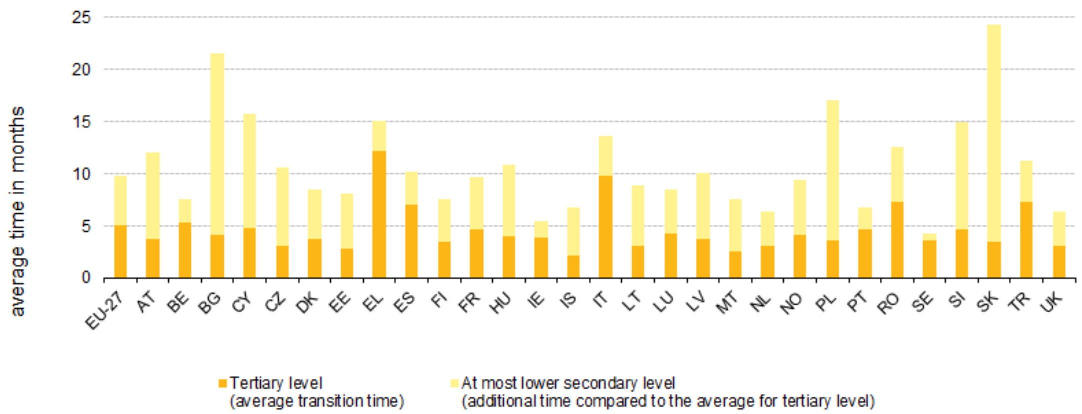
The average 2 years of work experience is gained cumulatively throughout the studies. It is very common for the students to work during the summerbreak. Universities tend to provide some courses for summer for the students that fail landing a summer job or prefer studying in the summer. Spending the summer studying is however quite often a backup plan for students: in the summer of 2016, 82 % of students in the field of technology were employed. Students also work quite a lot during the semesters with 53 % of students in the field of technology working at least occasionally during semesters in the academic year 2015-2016. The summer jobs tend to be full-time and jobs during semesters tend to be part-time. (TEK Student Survey 2016) The M.Sc. thesis in the field of technology is mostly conducted in employment which also contributes an average of 8 months to the work experience of graduates. Only 19 % of 2016 graduates received no compensation for their masters thesis and 54 % conducted their thesis in the industry.

Finnish M.Sc.'s in Technology and Architects are mostly already employed when they graduate as seen in Fig. 3. The rate of employment is even higher if we account for agreed but not yet signed job contracts at the time of graduation. The total average rate of employment of graduates in 2016 was 68 % including the agreed job contracts. Fig. 3 also highlights the importance of work experience in enhancing the employability of graduates: the more work experience the graduate has gained during studies, the more likely they are to be employed at the time of graduation.

	Not at all	Less than 1 year	1-2 years	More than 2 years
Seeking for a job	48%	29%	19%	11%
Agreed workplace	8%	13%	13%	8%
Valid work contract	37%	50%	63%	77%

Fig. 3. Employment and amount of work experience (excluding M.Sc. Thesis work) gained during studies of M.Sc. in Tech graduates in 2016. (TEK Graduate Survey 2016)

One of the advantages of gaining work experience prior to graduation is the reduced transition time from education to work. As seen in Fig. 4, the Finnish average transition time from tertiary education to work is the seventh fastest of the EU-27 comparison (Finland average 3.5 months vs. EU-27 average 5.1 months). The reason for the swift employment after graduation is explained to a large extend by the fact that graduates get employed to the organization where they have worked during studies as seen in Fig. 5. More than three out of four employed graduates have worked during studies in the same organization where they were employed at the time of graduation.



Notes: Results are based on people who left formal education in the last five years.
BG, LT and SI data lack reliability due to low sample sizes for the category "at most lower secondary".

Fig. 4. Average length of transition from school to work by educational attainment level (Finland = FI), fields of science combined 2009. (Eurostat)

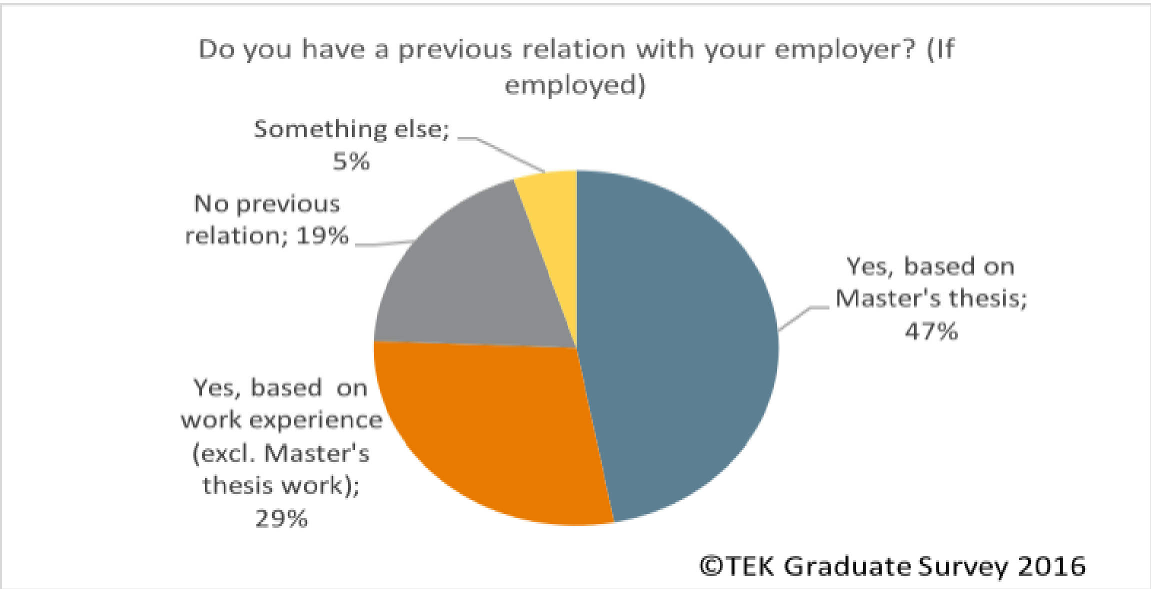


Fig. 5. Previous relation with employer, employed graduates 2016. (TEK Graduate Survey 2016)

The graduates also feel that the first position after graduation corresponds very well with their educational backgroud. Four out of five think that job corresponds either well or very well both with the graduates' field of studies and level of education. Due to intensive culture of working during studies, graduates tend to skip the trainee phase of employment after graduation as it is already taken care of alongside studies.

5 CONCLUSIONS AND DISCUSSION

In this paper we focused our study of work experience and employability in the graduates of engineering and technology. The amount of work experience gained during studies has a strong effect on the employability of graduates.

The Finnish higher education policy aims for shorter length of studies to lengthen the careers of graduates. That however seems highly unnecessary accoring to our data. The professional careers of graduates in the field of engineering and technology start already in the course of studies. The co-ops, CDIO concepts and traineeships are and can be embed in the engineering degrees through recognition of the skills and competencies gained outside of the classroom.

Learning to be an Engineer: Implications for the education system

ABSTRACT

Previous research has reframed engineering as a series of six engineering habits of mind (EHoM). This was seminal for shaping thinking around what knowledge, skills and competencies young people need to develop if the UK wants to produce more engineers. *Learning to be an Engineer* explores the ways schools can create better and more engaging learning opportunities for would-be engineers and how engineering EHoM can be integrated in the real world of busy schools and colleges. The overarching hypothesis was that, while it is necessary to continue to value disciplinary knowledge and practical skills, it is also important to think more about the dispositions engineers need to acquire. To do this, dispositional teaching and its associated learning methods were carefully considered.

The research identifies some essential elements of the signature pedagogy for engineering: the engineering design process, 'tinkering', and authentic, sustained engagement with engineers. It also describes many positive outcomes for learners taught in this way, including: increased fluency in the key habits of mind and the development of 'growth mindsets'. Additionally, it finds benefits to the capability and confidence of teachers, in particular their engagement with practising engineers.

Conference Key Areas: Engineering Skills, Curriculum Development, Engineering Education Research

Keywords: Dispositions, signature pedagogy, education

INTRODUCTION

Learning to be an Engineer follows an earlier piece of analytic research, *Thinking like an Engineer: Implications for the education system*, which reframed engineering as a series of 'engineering habits of mind' (EHoM): systems-thinking, adapting, problemfinding, creative problem-solving, visualising, and improving [1]. The most important finding from this research is that the question, 'how do engineers think?', seemed to matter to teachers of engineering and is one which had not been discussed much previously. The teachers really engaged with this question and it was very effective at opening up discussions regarding pedagogy. Understanding more about how engineers think can assist teachers of engineering to construct appropriate curricula and select pedagogies and assessment methods which support engineering. Furthermore, understanding more about how engineers think may also provide clues as to how engineering careers can be presented more effectively to young people [1].

Drawing on extensive research and informed by discussions with experienced engineers and engineer educators, we suggested a number of signature pedagogies [2]. At the core of these is the engineering design process.

This research involves a small-scale intervention study and documents a proof of concept trial that sought to establish how schools can adopt the EHoM framework, which teaching methods are most helpful and the impact of adopting this approach.

The research began in late 2014 and was completed in summer 2016. It involved 33 schools and one further education college, 84 teachers and over 3,000 pupils. Three partners were involved in the research and each partner designed a programme of support for schools to embed EHoM using a range of different approaches.

During the research period, schools in England went through a time of considerable change, affecting their status, curriculum and accountability. A major review of the National Curriculum [3] was completed in England, which affected primary and secondary schools, as teachers engaged with, among other changes, computing as a new subject. At secondary level, the English Baccalaureate (EBacc) was introduced [4] and two new accountability measures, Attainment 8 and Progress 8, were introduced from 2016 onwards [5].

1. OUR APPROACH TO THE RESEARCH

1.1 Our theory of change

In moving from our conceptual research to a series of interventions we articulated a theory of change (TofC) in *Table 1*.

If we

- reframe engineering education to include desirable engineering habits of mind (EHoM) in addition to subject knowledge, and
- clearly articulate the principles and practices through which these EHoM can be cultivated in schools, and
- offer teachers targeted support for changing practices along with opportunities to co-design enquiries within the context of a reflective professional learning community Then
- we can better understand what school leaders and teachers need to do to change their practices to embed more effective engineering education

So that

- we can share this understanding widely and
- more effectively support the process of successful implementation of engineering education in schools

So that

- more schools embrace engineering and

- more school students have high-quality experiences of engineering education and
- more students choose to study engineering beyond school and, potentially, choose careers in engineering.

Table 1: Learning to be an engineer – a four step theory of change

Essentially we are suggesting that to overcome our current lack of engineers we need to do three things in schools:

- Move away from a focus on disciplinary knowledge (subjects such as maths) towards a better understanding of the ways engineers think and act (EHoM)
- Describe the teaching and learning methods most suited to cultivating EHoM, and
- Build teacher capability through professional development.

Our over-arching hypothesis is that while we need to continue to value disciplinary knowledge and practical skills, we also need to think more about the dispositions we want our engineers to acquire.

1.2 Research design and methods

The methodology for this small-scale intervention study was designed in line with our TofC model. We have previously identified the six EHoM and articulated possible approaches to their cultivation [6][7]. This report builds on this and presents the outcomes of a small-scale intervention study aimed at exploring the process of implementing EHoM in primary and secondary schools, and to a lesser extent with 16 to 19 year olds in further education colleges.

The schools and college participated on a voluntary basis and their teachers engaged in a small test of change to explore how they might expand engineering in the curriculum and cultivate EHoM in their learners. The majority engaged with this as a CPD learning project for which they adopted a participatory action research approach [10], evaluating the impact of their interventions on their learners, on themselves and on their school using a number of methods.

1.3 Evaluation methods

We used a number of qualitative methods to explore the teachers' intervention experiences to ensure as much triangulation of data sources and types as possible. This involved teachers' evaluations of their action research interventions, semi-structured interviews with teachers, and qualitative feedback via a questionnaire. We adopted an appreciative inquiry approach (AI) to underpin our philosophical approach to the whole study [9].

1.4 Data analysis and reporting

To understand more about the pedagogic processes underpinning the successful cultivation of EHoM in schools and to learn more about the impact that these interventions have on learners, teachers and engineers, we used a 'realist synthesis' approach [10] to identify why the teachers' interventions worked (or did not) and in what contexts. Analysis of the data using techniques associated with realist synthesis offered the opportunity of establishing not simply 'what works' but also 'for whom' and 'under what circumstances'. This perspective, with its explanatory rather than judgmental focus, also aligned with our AI philosophy.

We used thematic analysis [11] to code the data and produced a synthesis of the ways in which teachers had cultivated EHoM. We looked for patterns, identifying issues which were frequently repeated in the data but not specific to any one sector, such as 'learning from failure' or factors associated with 'growth mindset'.

Given the short length of time during which most teachers' interventions were carried out, and the variety of locations, there are inevitably limitations on the extent to which we can generalise from our findings. However, our use of realist synthesis allows us to offer an explanatory analysis of the degree to which the different interventions did or did not work and make some general remarks about these.

2. THE STUDY

2.1 Overview

The three partners each developed a distinctive approach to using the EHoM framework but all explored pedagogies for EHoM, curriculum development and teacher professional development. All the partners encouraged teachers to use participatory action research to structure and evaluate small tests of change in classrooms. The three projects undertaken were: Thinking Like an Engineer (TLaE), Tinker Tailor Robot Pi (TTRP), and Primary Engineer in Scotland.

2.2 Thinking Like an Engineer (TLaE)

This project embedded EHoM into the curriculum in a small number of schools and a college in England. TLaE developed teachers' understanding of EHoM, supported teachers in using signature pedagogies to develop EHoM and in creating schemes of work that included EHoM across science, mathematics, computing, D&T and art, and encouraged teachers to draw on the expertise of practising engineers. TLaE involved a blend of training, school support, curriculum development and action research as part of a professional learning community.

2.3 Tinker Tailor Robot Pi (TTRP)

This project investigated the development of an ethos of tinkering within computing, D&T and the science curriculum to promote engineering and EHoM with schools in Greater Manchester. TTRP explored how a pedagogical approach to primary engineering could be established within the mainstream curriculum. TTRP encouraged the sharing of professional practice between teachers and engineers, explored how engineers work and how learning related to engineering is taught in primary schools, and identified opportunities for incorporating engineering in primary schools through science, D&T and computing.

2.4 Primary Engineer

In 2015, work began to develop one of Primary Engineer's teacher development programmes into a GTC Scotland Professional Recognition Programme in Engineering STEM Learning which is now accredited by the University of Strathclyde as a Postgraduate Certificate. This third project supported the delivery of the course aimed at primary teachers in Scotland during 2015–2016. Nine teachers from eight primary schools in Glasgow and East Ayrshire completed four assignments, one of which involved interviewing engineers to explore the growth of their EHoM.

Figure 2 below shows the key features of the three interventions diagrammatically.

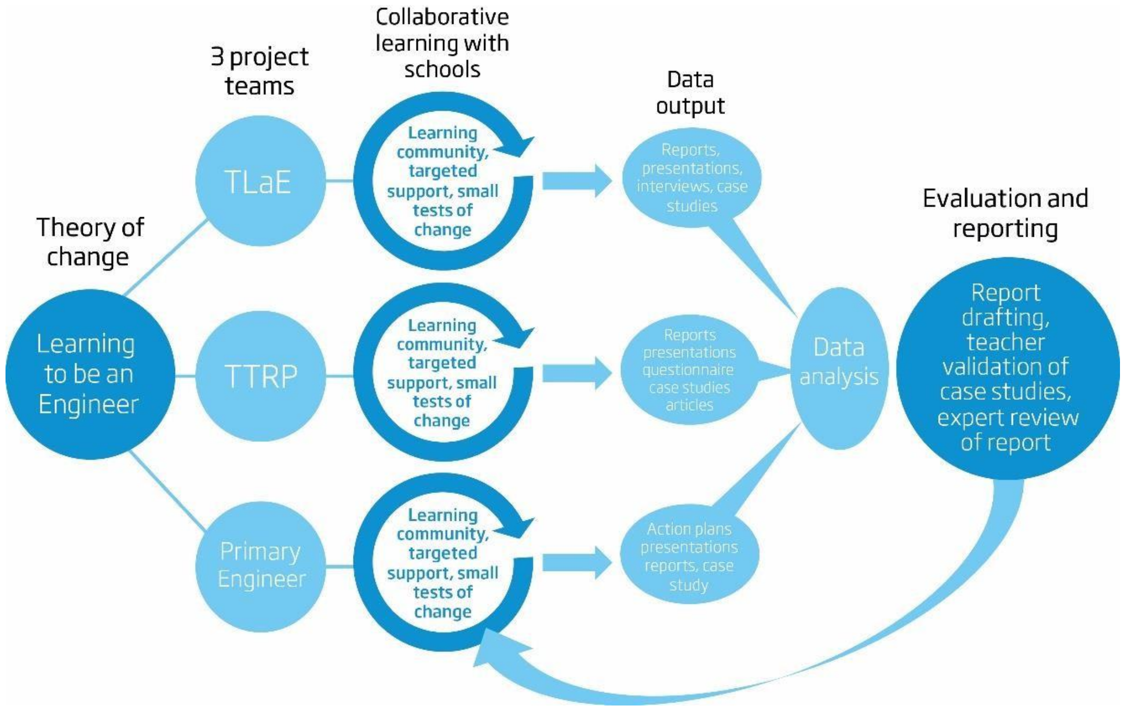

Figure 2: Overview of the three project interventions

3. CULTIVATING ENGINEERING HABITS OF MIND

Four pedagogic principles guided our cultivation of effective learning habits:

1. Teachers and learners need to fully understand the habit and recognise it when it is being used successfully.
2. Teachers must create the climate for a habit to flourish, including rewarding it.
3. Teachers need to choose teaching methods that facilitate the practice and transfer of the habit.
   One of the aims of our programme was to explore the value of 'signature pedagogies' in cultivating EHoM [2], teaching methods most likely to develop the desired engineering habits. The three elements of a signature pedagogy we explored were: the engineering design process, 'tinkering' (an approach to playful experimentation), and authentic learning with practitioners, such as professional engineers.
4. Teachers need to build learner engagement and commitment to the habit.

This research strongly validates the first step of our TofC. Teachers and engineers understood, approved of and used the EHoM model. They were able to connect EHoM thinking to their current practices and to the shifting external educational environment. They liked and used the signature pedagogy thinking. They responded enthusiastically to being part of a supportive professional learning community, were able to co-design different curricula using new pedagogies and were able to begin to make changes to their practices.

4. OUTCOMES FOR LEARNERS

In this section we describe the impact of teachers' interventions on their learners. We focus on the degree to which learners were able to use EHoM, the development of engineering mindsets, impact on literacy, numeracy and oracy, on classroom management and on learners' understanding of engineering.

4.1 Growth in learners' fluency with habits of mind Teachers observed growth in learners' fluency with the six engineering habits of mind: systems-thinking, adapting, problem-finding, creative problem-solving, visualising, and improving.

4.2 Evidence of developing engineering growth mindsets

In many cases, before the EHoM interventions, teachers said learners lacked resilience, perseverance and self-efficacy and were easily discouraged by failure, showing a fixed rather than a growth mindset. But as the project progressed, teachers reported that learners got better at using EHoM the more they practised them and that they demonstrated an increased growth mindset more generally. They also observed pupils transferring these skills in other areas of the curriculum.

4.3 Impact on literacy, numeracy and oracy

While we did not specifically aim to investigate the impact of cultivating EHoM on attainment in literacy and numeracy, some primary teachers noticed improvements in these subjects.

Teachers also reported that learners demonstrated an increased fluency in expressing ideas or opinions. Oracy, learning to talk well and learning well through talk, is regarded by many primary teachers to be of equal importance with literacy and numeracy in supporting attainment [12]. At secondary level, teachers noticed an improvement in learners' communication skills that was more employment focused. Learners demonstrated an increased confidence to network with employers and were able to talk in a more convincing manner to them when they went for job or apprenticeship interviews.

4.4 Self-managed learners and impact on classroom management

Overall, teachers reported that children were enthusiastic and motivated and that attitudes towards learning improved during the EHoM sessions. Teachers described how children had more opportunity to 'discuss, evaluate, analyse and problem solve' and that by working together on a 'level playing field' they were able to demonstrate EHoM. Some teachers found the approach took longer and noted that some more academic children found this type of learning challenging and struggled with the creating process. However, less academic children had a 'chance to shine' and demonstrate greater self-management.

4.5 Impact on learners' understanding of engineering

EHoM teaching that was reinforced through modelling by engineers enhanced learners' understanding of engineering and its potential as a career. The engineers' involvement in the curriculum showed learners how the content and skills they were learning were directly relevant to the real world.

5. OUTCOMES FOR TEACHERS

In this section we explore the impact on teachers' own habits and practices, as well as reflecting on the ways in which they engaged with engineers.

5.1 Teachers as risk takers and improvisers

It was evident that teachers found changing the habit of being 'in control of adverse events' and 'the expert' extremely difficult. Those who managed this shift found it to be very beneficial. More significant and riskier behaviour changes for teachers, such as admitting mistakes or being open-minded when receiving learners' ideas, were evidence of further development of the teachers' own growth mindset.

There were numerous occasions when teachers explained how they learnt alongside their students, particularly when they were addressing the meaning of the EHoM and attempting to transfer the use of EHoM into subjects other than engineering. They became more skilled at engaging in ‘cognitive apprenticeship’ style teaching techniques, such as modelling, scaffolding and coaching [13].

5.2 Teachers as collaborators

In most cases teachers were working on their interventions in pairs or groups, so had many opportunities to learn from each other. In secondary schools EHoM brought teachers from different departments together resulting in increased subject integration. Some teachers became recognised within and outside their school as ‘the expert’ on EHoM and on incorporating engineering into the curriculum, offering CPD sessions to their colleagues.

5.3 Teachers as reflectors

The action research approach underpinning the evaluation of the teachers’ EHoM interventions encouraged them to reflect on their methods. This led to further thinking about how to adapt their traditional teaching strategies, which was most evident in two areas: their increased use of facilitation techniques and the enhancement of their questioning techniques. Teachers also became more skilled at facilitating discussion and helping learners generate ideas through good questioning.

5.4 Teachers’ confidence in engaging with engineers

Though using EHoM, teachers gained knowledge that gave them confidence to make links between the subjects and skills that they were teaching and the world outside the school. Teachers’ growing understanding of EHoM also appeared to increase their confidence in approaching engineers about coming into the classroom and contributing to the curriculum.

The experience encouraged curriculum managers to be more direct with employers about how their involvement with a college can be mutually beneficial. Teachers also listened to what engineers were telling them about what it is like to work as an engineer and how teaching needs to change to cultivate this style of thinking.

6. CONCLUSIONS

This series of coordinated, small-scale interventions, piloted across a number of schools in three different regions of the UK, emerged from a reframing of what it is to be an engineer and research into how teaching and learning methods can best be selected to cultivate certain EHoM. Teachers undertaking these changes were given targeted support within a wider professional learning community in which there were opportunities for them to co-design new ways of teaching. In this section we draw conclusions from our evaluation of the teachers’ activities and discuss implications for different stakeholders.

Our ToC defined our overarching hypothesis that dispositional teaching using appropriate pedagogies could develop in young people the habits of mind most valuable for engineers. Furthermore, given targeted support for professional learning, teachers could adopt these pedagogies to enthuse young people about engineering.

Our findings suggest that within schools wanting to implement more engaging engineering education, the three elements of the first step of our TofC are valid:

a) The reframing of engineering education within schools in terms of EHoM in addition to subject knowledge is something that teachers like and understand.

b) It is possible to create the climate for EHoM to flourish at Key Stages 1, 2 and 3 using three elements of a signature pedagogy for engineering – the engineering design process, tinkering and authentic engagement with engineers – to cultivate the desired engineering habits of mind.

c) A professional learning community that offered targeted support for teachers to design, implement and reflect on the impact of small-scale curriculum interventions in a range of different subjects did begin to change their practices.

With reference to the second step of our TofC, we have begun to better understand what school leaders and teachers need to do to embed their practices. We draw the following additional conclusions:

1. EHoM approach – With support, all schools managed to use the four-step process for cultivating EHoM, locally interpreted and adjusted according to learner age and context. The least developed EHoM was systems thinking.

2. Developing as learners – As well as acquiring more confidence and capability in the target habits, there were significant improvements in terms of mindset (perseverance, learning from mistakes, playful experimentation) and the development of confidence as independent learners. The approach produced significant improvements in learners' understanding of engineers and engineering.

3. Professional learning – The mutually supportive environment of a professional learning community coupled with supported opportunities for the designing of smallscale tests of change was helpful in enabling teachers to begin to change their habits. But even in a supportive environment, teachers found it difficult to relinquish some of their former practices.

4. Leadership – The effective cultivation of EHoM requires a school culture supportive of exploring habits of mind and using interactive pedagogies, complementary summative and formative assessment practices, practical timetabling, appropriate physical space, available local engineers, and proactivity by senior leaders. Effective school leaders recognised the commitment and investment necessary to bring about a wholesale culture change.

5. Engaging with engineers – Engineers were most effectively engaged when they had an ongoing relationship with the school, which included extended conversations with teachers, working directly with young people, hosting visits for pupils and parents in their workplaces, and participation in the professional learning of teachers. Extended contact between engineers and schools makes learning relevant and provides adult role models to convince learners and their parents of the value of engineering as a career. In terms of the third step of our TofC, we have begun to document the extent of the challenge and understand how some external changes might facilitate progress.

In terms of the fourth step we still have a long way to go. Specifically, we need to understand more about successful models of the leadership of the necessary changes required at all levels of the education system.

ABSTRACT

Through tutorials, students can develop their engineering and professional skills outside taught modules. We introduced a new integrated tutorial system in which students were taught in mixed year groups. Questionnaires and focus groups were used to investigate whether students preferred integrated tutorials or tutorials in their year groups. There was a clear preference for integrated tutorials, with students feeling that they provided improved pastoral and academic support and were more stimulating. They particularly appreciated the opportunity to mix with students from other years in a learning community. A minority of students felt that mixing the year groups meant that less material was relevant to individual students than in single-year group tutorials. Overall, integrated tutorials were felt to offer a more supportive learning experience than traditional year-group tutorials.

INTRODUCTION

Tutorials provide an essential opportunity for students to consolidate knowledge gained in taught modules (sometimes referred to as courses or units) and to generalise their learning by discussing real-world engineering problems. Tutorials take many forms depending on the institution, the discipline and individual academics' preferences. Here, we define a tutorial as a regular opportunity for students to meet with staff for guidance on academic and personal matters that are broader than those discussed in individual modules. Our institution accepts that personal tutorials differ across disciplines; therefore, our tutorials focus on discussing employability skills, relevant resources and upcoming events.

Tutorials fill numerous overlapping roles including providing academic support, pastoral support, a learning community, peer learning, a social support network and so on [1]. Much of this could be provided by a tutorial system which is not discipline-specific. Indeed, the benefits of a learning community and social support network could even be enhanced by cross-disciplinary tutorials. However, discipline-specific tutorials can offer relevant advice which is consistent throughout an entire degree programme including the selection of optional components, specific advice on internships and careers, and the opportunity to develop professional engineering skills [2,3], as well as allowing open-ended student-led discussions about current engineering practices [4].

We recognise the broad range of activities which are referred to as "tutorials" and here take the opportunity to define our tutorial system. Our system is based on discipline-specific pastoral tutorials. Purely academic tutorials are given by subject-experts as part of taught modules. This ensures that all students on a module (who might come from different degree programmes in different departments) benefit from the same academic support. Here, we consider pastoral tutorials which are given in groups of about 10 students with a discipline-specific academic staff member. Where possible, the same staff member acts as tutor throughout the students' degree programme. We aim to have about 10 one hour tutorials per year, while encouraging students to arrange additional one-to-one meetings with their tutor where necessary. The topics covered are flexible but typically include professional engineering skills, preparation for employment, and revision and examination techniques.

In this paper, we compare two different tutorial systems, both following the general principles detailed above.

1 TUTORIALS AND LEARNING COMMUNITIES

1.1 The role of tutorials in an engineering programme

Tutorials provide an additional learning platform for students which complements more formal sessions, providing a further type of learning which goes beyond the formal lectures, project/problem based learning, and practical group work which take place elsewhere in an engineering programme. Students may be encouraged to discuss cross-cutting engineering themes which apply across subjects and which might be currently topical. They are informal and unassessed opportunities for students to engage in relevant topics [4] and they help to consolidate professional engineering skills such as teamwork, communication skills and an appreciation of broader contexts of engineering [5].

1.2 Learning communities for support and professional development

An important function provided by tutorials is the opportunity for students to develop a learning community [1,6,7]. This recognises that learners work together in a social group, gaining both social and academic support from each other whilst learning together. There is convincing evidence that “moderate to large academic benefits can be attributed to peer tutoring” [8]. Furthermore, newcomers to a group may gain particular benefit from working with established members of the group [9].

1.3 Integrated tutorials

In our previous tutorial system in a new 3-4 year biomedical engineering undergraduate programme, students were divided into tutorial groups, each of which consisted only of students from a single academic year. This brings undoubted advantages as the learning and interventions which students require tend to change year-by-year. All tutorials can therefore be focussed and are equally relevant to all students.

However, this system provided students with limited opportunities to *meet* with students from other year groups and almost no opportunities to *learn* with students from other years. Indeed, it was postulated that final year students underestimate their learning and maturity because they find it hard to compare their current level of knowledge to that which they had when they entered the programme. We decided to tackle this problem with a solution inspired by a local secondary school which has successfully introduced a “vertical”, mixed-age tutorial system which “encourages students from all ages and groups to mix and socialise well” [10].

In our new, “integrated tutorial” system, two to three students from each year group make up a tutorial group of about 10 students. The tutor acts more as a facilitator than an expert and can encourage conversation between the students. A few single-year-group tutorials remain where we need to address topics which are specific to a single year group. We assessed the impact of the integrated tutorial system using a combination of questionnaires and focus groups in a new collaboration between tutors on the biomedical engineering programme and the Institution’s Teaching and Learning Centre.

2 METHODOLOGY

2.1 Questionnaires

A questionnaire (*Fig 1*) was prepared, based on a 5-point Likert-type scale, designed to offer a quantitative comparison of students’ opinions of the new integrated tutorial system to their opinions of individual year tutorials. It included 12 questions designed specifically to assess tutorials (shown in Fig 1) and 10 more general questions aimed at assessing students’ opinions of the overall degree programme (not shown). Some questions were intended to be similar e.g. “how valuable are tutorials?” and “what is your overall view of tutorials?” in an attempt to provide some internal consistency check. The order of the five points on the Likert-type scale was randomised so that some questions were ranked good-bad and others bad-good. All were corrected so that 1 was bad and 5 was good before analysis. The questionnaires were anonymous, but students were asked to state their year group.

There is considerable controversy in the literature over the analysis of Likert-type data, depending on whether the categories are assumed to be equally spaced intervals, and if so whether the data can be assumed to be Normally distributed or not [11]. Here, we follow the lead of the UK's National Student Survey, where positive answers (e.g. "agree" and "strongly agree") are added together and expressed as a percentage "satisfaction" score.

Tutorials:

		1	2	3	4	5	
How many did you attend?	None						All
How useful were they academically?	Very useful						Not useful
How useful were they for personal development?	Not useful						Very useful
How relevant were they to taught material?	Highly relevant						Not relevant
How did they prepare you for scenarios, minors, etc?	Not at all						Fully
How useful were they for internships, careers advice, etc	Very useful						Not useful
How stimulating were tutorials?	Very						Not at all
Do you have sufficient academic support?	Yes						No
Do you have sufficient pastoral support?	No						Yes
Was your tutor available outside tutorials?	Yes						Hardly at all
How valuable are tutorials?	Not at all						Extremely
What is your overall view of tutorials	Very useful						Pointless

Fig 1. The Likert-type questionnaire which students were asked to fill in to assess their opinions of tutorials.

2.2 Student focus groups

Qualitative data provided cross-year focus groups to gain a deeper understanding of students' experiences of the new tutorial system. Five students took part in discussions in the focus groups, which expanded on the questionnaire responses in order to yield more information. One limitation of this study is the small number of students taking part in the study due to scheduling conflicts. While the number is small, our findings provide an initial cross section of feedback to be studied further.

3 RESULTS

3.1 Questionnaires

22 students completed the questionnaire for the single-year tutorials and 28 for the integrated tutorials (in the latter, 14 were from year 1, 8 from year 2 and 6 from year 3). The satisfaction scores (percentage of scores of 4 or 5) are given in Fig 2. Similar questions (e.g. Q11 and Q12), and another set of questions which on the same sheet but which were not intended to test for differences between the tutorial systems, had an average absolute difference between the systems of 7%, so this was taken to be a measure of the uncertainty and any differences between the years of greater than 14% was deemed worthy of further examination. These are highlighted in bold in Fig 2.

Two questions (Q1 and Q10) were rated more positively under the old single-year tutorial system, and the remainder were more positively rated under the new system. All of the changes >14% corresponded to improvements of the new system over the old one, with the average difference over all questions being 12%. Attendance was similar across both systems.

	Tutorials	Single-year tutorials	Integrated Tutorials
1	How many did you attend?	91	86
2	How useful were they academically?	**18**	**46**
3	How useful were they for personal development?	55	57
4	How relevant were they to taught material?	23	27
5	How did they prepare you for scenarios, minors, etc?	55	46
6	How useful were they for internships, careers advice, etc	**36**	**75**
7	How stimulating were tutorials?	**41**	**57**
8	Do you have sufficient academic support?	**62**	**86**
9	Do you have sufficient pastoral support?	**50**	**82**
10	Was your tutor available outside tutorials?	91	82
11	How valuable are tutorials?	45	54
12	What is your overall view of tutorials	52	61

Fig 2: Percentage satisfaction scores for two tutorial systems, with notable differences highlighted in bold

3.2 Student focus groups

When students were asked what is beneficial about the integrated tutorial system, their responses could be placed in two categories: academic and personal. Academically, students appreciated learning about modules and getting advice from students in other year groups. They saw other students as an unbiased source of information about modules and assignments. Personally, they saw the integrated tutorial as an opportunity to meet other students in the programme; it encouraged conversations between year groups and provided informal pastoral support. They particularly appreciated meeting like-minded students working in the same field.

Students suggested academic improvements that will be taken in to consideration (*e.g.* “more opportunities to talk to students from other year groups”), as well as practical issues around timetabling and very specific suggestions such as more assistance with writing job and internship applications. They particularly appreciated sessions that described practical engineering opportunities such as options for internships.

Overall, they felt that the integrated tutorial system led to more discussion among students, but a minority, particularly third-year students, felt that a reduced proportion of the time spent in tutorials is relevant to them, as much of the content might be relevant to students in other year groups.

4 DISCUSSION

On the whole, students preferred the new integrated tutorial system to the original single-year tutorials. However, their reasons were not those that we anticipated when we introduced it. The original aim was to provide students coming to the end of their degree with a comparison so that they could see how much they had learnt. This did not appear to be seen as relevant by either the questionnaire responses or the focus groups. Indeed, the main advantage was seen to accrue to new students who appreciated the opportunity to engage with and learn from more experienced students.

The results of the questionnaire showed that students did prefer the new system and felt it offered improved pastoral and academic support. They also felt that integrated tutorial conversations offered better advice on careers and internships. One of the strongest responses from the focus groups agreed with the response to Q7, namely that the tutorials were more stimulating because students engaged in conversation with each other. It is clear that students see the supportive, affective aspect of tutorials as very important – academic and pastoral support gained the highest satisfaction rating of all the questions. This aspect of community has been described in the literature [1,4,7] but its importance is perhaps under-recognised by practitioners.

There were substantial practical difficulties with the integrated system, mainly due to the challenging requirement to timetable sessions when students from all year groups can attend. It is also necessary to give more thought to planning and co-ordinating each session to ensure relevance to all students and so that all students receive a similar experience.

Advantages to staff of the new system include the transfer of expertise from tutor to student. The tutor's role has moved from being the source of information to a facilitator, encouraging students to discuss and solve problems themselves. This reduces the programme-specific experience needed for staff to get involved in tutoring and allows a wider range of staff to get involved.

One interesting suggestion which came from discussion with students is to allow them more influence over what topics are covered in tutorials. We will continue to develop our tutorial programme and encourage students to take an active role in planning tutorials as well as engaging in them.

5 SUMMARY

We have reconfigured the tutorial support system in an undergraduate engineering degree programme so that each tutorial group includes students from all years. Results demonstrated that overall students preferred the new tutorial system, though newer students were more in favour than students coming to the end of their programme.

We propose to continue to develop the integrated tutorial system, taking account of students concerns and suggestions as we do so.

6 ACKNOWLEDGMENTS

We are very grateful to the students and the staff who supported this study.

ABSTRACT

English Medium Instruction (EMI) is a commonly accepted and adopted approach to internationalization of universities. Internationalization involves both staff and students, as they both tend to benefit from the use of English in courses. This study compares two video-recorded lectures in an engineering master's program. These lectures were transcribed and student feedback was collected on paper-based questionnaires immediately after attending the recorded lectures. Students were asked to evaluate both their own English competency (self-evaluation) and their lecturers' English competency. This paper focuses on whether 1) the lecturer's English competency key to students' comprehension and 2) there is a link between student's English competency and their comprehension of these lectures.

The results indicate that the lecturers' English competency, as evaluated by the students, for these two lectures was almost identical. Despite this, the comprehension level of these lectures was notably different. Nevertheless, students' self-evaluation of their English competency did not appear to be a distinguishing feature regarding lecture comprehension. Closer examination found more use of interactional features in the better comprehended lecture. While research is attempting to find the "good enough" level of English, the lecturers should focus on implementing enough interactional features when lecturing for better comprehension of their lectures.

Conference Key Areas: Engineering Education Research, Skills and Engineering Education, Curriculum Development

Keywords: English Medium Instruction, English competency, lectures

INTRODUCTION

English Medium Instruction (EMI) is a commonly accepted and adopted approach to internationalization of universities. Internationalization involves both staff and students, as they tend to benefit from the use of English in courses. These benefits may not be evident at the point when lecturers are converting and developing their courses and their materials into English and, especially at the beginning of EMI, need to use more time on course work than when doing it in their native languages. What level of English, then, is "good enough" for lecturers? Students, naturally, have to take TOEFL or other standardized exams to show their ability to study in English before acceptance to a study program. Usually lecturers are not required to do so, especially if they already have their permanent positions and if they have established themselves as experts within their field of study.

Since acquiring knowledge on EMI in engineering education, [1] found benefits, such as more immediate and concentrated focus on the subject matter as well as concentration in general, for lecturers and students. The present study compares two video-recorded lectures in an engineering master's program. These lectures were transcribed and student feedback was collected on paper-based questionnaires immediately after attending the recorded lectures. Students were asked to evaluate both their own English competency (self-evaluation) and their lecturers' English competency. This paper focuses on whether 1) the lecturer's English competency is a key to students' comprehension and 2) there is a link between student's English competency and their comprehension of these lectures. The study attempts to see what other issues may influence the level of comprehension, although it avoids a more thorough linguistic analysis as that would be beyond the scope of this particular conference.

1 INTERNATIONALISATION, ENGLISH, AND COMPREHENSION

1.1 International universities

Currently, most European universities (of technology) have much of their courses offered in English [2]. It is one way to attract both international staff and students which is evaluated positively in the university assessment in reference to the level of internationalization of the university. When this trend was initiated at the beginning of the current millennium as part of the Bologna process[1], discussions varied from students not being able to learn through English to how they will learn both the subject matter and English simultaneously. Some student unions highly criticized the courses being offered in English only rather than in both English and in the major native language of the university in question.

Today Master's Programs in English are the norm and even some Bachelor's Programs, or at least courses, are operated in English in countries where English is not considered the native language. Despite this, many non-native English speaker lecturers still feel unsure of their language abilities and have concern whether their students understand them when they use their "broken English" in lecturing.

1.2 English as a Lingua Franca (ELF) and lecturing

Lingua francas have been used at least from 1200's when the Arab-speaking traders had to communicate with "Franks", i.e. the Europeans to conduct business. The developed "language of the Franks" (=lingua franca) enabled these business transactions to occur [3]. Since this original *lingua franca*, the term has been reserved to those native languages which are used as a vehicular language in situations where no other common language is found.

According to Seidlehofer [4], non-native speakers of English use ELF mostly with other non-native speakers of English. These non-native speakers of English have outnumbered the native speakers already for decades [5], [6] and English is the language of science, academia, business, and (popular) culture. Usually the situations in which English is used, are high-stakes situations in which participants aim at comprehensive communication regardless of the potential obstacles.

---

[1] See, e.g. http://www.coe.int/t/dg4/highereducation/EHEA2010/BolognaPedestrians_en.asp#P132_13851

Lecturing is a good example of a high-stakes situation and, no matter what we may think of the efficiency of lecturing as pedagogical means to learning, still a major part of instructional activities at universities [7]. With the internationalized universities, these lectures are most often held in ELF with audience whose native languages vary. In addition to the most obvious function of a lecture, relaying information, it also has other functions, such as focusing on a common goal, preparing for working life, as well as socializing students into the scientific community and even preparing them for working life [8], [9], [10].

1.3 Lecturing and Comprehension

Measuring comprehension is a difficult task. Tests, if designed properly, show what students know. The testers cannot know, however, where and how this knowledge was acquired and whether that knowledge relates to comprehension of prior lecturing.
What is known, though, is that reading written text aloud is usually more difficult to comprehend than spontaneous spoken language [11]. This explains the promotion of the so-called conversational style lecturing [12] – also called fresh talk [13] and open style lecturing [14] – in order for the audience to be able to follow and comprehend the lecturing. This type of lecturing is close to spoken language rather than written text and even allows better activation of the audience, another means to aid comprehension.

According to [15], lectures in the English-speaking universities are becoming less formal and more interactive and the role of the lecturer is more of a facilitator. [16] recommend lecturers to encourage their students to be active rather than passive. These approaches, regardless of the language used in lectures, helps students to comprehend the lectures.

When lectures are in English, which is neither the lecturer's nor the student's native language, the assumption is that communication is not very fluent. Nevertheless, [17] and [18] found that ELF speakers tend to use communication strategies to explicate their message. This, in addition to other EMI features would support the learners when attending lectures conducted in English as a *lingua franca*. In other words, lecturers may subconsciously be using strategies to help their audience to comprehend their messages.

2 CASE STUDY ON LECTURES IN ELF

2.1 Background to the study

When universities modify anything, very often the first reaction of both staff and students is resistance to changes. When a Master's Program is reformed to be in English instead of the native language as it used to be, opposition is evident. Seasoned professors together with students who had been studying their Bachelor's Degree towards that particular Master's Program only to hear they will have to use English instead of their native language created a somewhat tense situation.

In order to determine students' perception of the new situation and the use of English, 22 lectures were video-recorded 2005-2006[2] with student feedback on paper-based questionnaires collected after each of these lectures [19]. Specific lectures were later chosen for closer scrutiny and transcribed. This paper focuses on two of the transcribed lectures and explores the feedback gathered on them.

[2] The material was collected over ten years ago and the situation currently may be somewhat different. Nevertheless, data itself is still useful and not outdated and, thus, provides valuable information when studied from various points of view.

Since the study is on a Master's Program in a somewhat small department, the lecture attendance was fairly low. Despite the low number of respondents, the questionnaire answers were able to shed light on the most intriguing lectures which then were studied further. The attendance influences the results of the study mainly in their generalization, but provide student point of view on the situation together with information on lecture comprehension.

2.2 Questionnaire

The entire questionnaire is available as Appendix 1. In addition to the statements regarding the respondent self-evaluated English skills and the perceived English skills of the lecturer, this paper focuses on the statements regarding comprehension listed in *Table 1* below.

Table 1. Questionnaire questions included in evaluation

		Agree	Somewhat agree	Somewhat disagree	Disagree
7.	I understood the contents of the lecture well.	1	2	3	4
8.	I did not understand the main contents of the lecture.	1	2	3	4
15.	It was easy to follow the lecture.	1	2	3	4

Although statement number 15 in Table 1 does not specifically mention comprehension, the ease in which student follows the lecture is seen as relating to the experience of understanding. Students also had to choose what they felt was their own level of English skills as well as those of the lecturer the lecture of which they had attended immediately before filling out the questionnaire. The scale for English skills was excellent, good, fair, and poor.

This paper explores the questionnaire responses and transcriptions of two lectures that were found to be the outliers of the lectures in a larger study [19]. Based on the comprehension values and perceived English skills calculated from the questionnaire responses, lecturers in Lectures 02 and 21, discussed in this paper, had almost identical English skill levels as perceived by the respondents while the comprehension levels differed quite notably. This difference intrigued closer inspection of these particular lectures.

2.3 Results

Lecture 21 had 19 participants, one of which did not complete the questionnaire completely and had to be disregarded. Lecture 02 had 9 participants, all of whom completed the questionnaire. The numbers are used only to show trends and to provide some basic information, naturally this is not a quantitative study as the quantities are so limited. Nevertheless, numbers and their analysis shed light on how students as a group of respondents reacted to the questionnaire statements.

Table 2 below shows the respondents viewed their own English skills and their lecturers' English skills. The group of respondents is different in these two lectures, but the responses regarding English skills is quite similar.

Table 2. Perception of English skills in two lectures

Lecture 21

Responses	Student Own English skill	Lecturer English skill
2	Excellent	Fair
6	Good	Good
8	Good	Fair
1	Good	Poor
1	Fair	Good

Lecture 02

Responses	Student Own English skill	Lecturer English skill
1	Excellent	Good
2	Good	Good
3	Good	Fair
1	Good	Poor
1	Fair	Fair
1	Poor	Fair

Most of the students self-evaluated their own English skills as being "good" while the English skills of these two lecturers were mostly assessed as being "fair". In Lecture 02, one student perceived their own English as "poor" while perceiving the lecturer's English skills as "fair".

Lecture 22 also had one student with "fair" skills but in this lecture the lecturer's skills by this student were perceived as "good". In Lecture 02 both the participants and the lecturer's English skills were perceived slightly worse than in Lecture 22. In both lectures those students who evaluated their own English skills being lowest in the group ("fair" or "poor"), both perceived their lecturer's skills one category higher than their own. However, those students who had self-assessed their own skills as "excellent" perceived their lecturer's English skills at least one category lower than their own ("good" or "fair").

How do the English skills reflect on comprehension of these lectures? Table 3 below shows participant responses to the chosen comprehension-related statements and the findings show more differences than those regarding English skills.

Table 3. Comprehension-related responses of lectures in percentages

		Agree	Somewhat agree	Somewhat disagree	Disagree
	Lecture 21				
7.	I understood the contents of the lecture well.	61	39		
8.	I did not understand the main contents of the lecture.			6	94
15.	It was easy to follow the lecture.	44	50	6	
	Lecture 02				
7.	I understood the contents of the lecture well.	22	56	22	
8.	I did not understand the main contents of the lecture.	11		22	67
15.	It was easy to follow the lecture.	22	45	33	

The first statement*, "I understood the contents of the lecture well"* had no respondent in Lecture 21 even somewhat disagree while 22% of the respondents somewhat disagreed with that statement in Lecture 02. Furthermore, even those respondents who were on the positive end of the scale, in Lecture 02 more "somewhat agreed" rather than agreed. This indicates the comprehension rate was notably higher in Lecture 21.

None of the respondents in Lecture 21 "agreed" or "somewhat agreed" on *"I did not understand the main contents of the lecture"* while 11% of the respondents in Lecture 02 "agreed" with that statement. In Lecture 21, 94% of the respondents disagreed with this statement and in Lecture 02 this number was 67%.

Statement *"It was easy to follow the lecture"* divided the respondents' opinions more in Lecture 02 where the responses are fairly evenly spread between "agree", "somewhat agree" and "somewhat disagree". In Lecture 22 only 6% of the respondents "somewhat disagreed" with that statement and 56% somewhat agreed.

Based on these responses, Lecture 21 can be viewed as a better comprehended lecture, although the English skills of both of the lecturers were assessed to be quite similar.

As with any study, outliers raise interest. In both explored lectures, there were those respondents who assessed their own English skills lower than those of the lecturers. When looking at their responses regarding comprehension, the responses are identical and not at the far ends of the scale. Both agreement and disagreement were "somewhat", as Table 4 indicates.

Table 4. English skills vs. comprehension

Lecture	Own English	Lecturer English	Understood well	Did not understand	Easy to follow
21	Fair	Good	2	3	2
02	Poor	Fair	2	3	2
21	Excellent	Fair	1	4	2
02	Excellent	Good	1	4	1

Scale: 1=agree, 2=somewhat agree, 3=somewhat disagree, 4=disagree

When looking at those respondents who assessed their own English skills as excellent, both felt they understood their lecturers well and disagreed with the *"did not understand"* statement. The respondent who perceived the lecturer's English skills as "Fair", found that lecture somewhat easy to follow while the respondent in the other lecture, who assessed the lecturer's English as "Good", found that lecture easy to follow.

These results indicate that the English skills of neither the lecturer nor the student. This demonstrates that comprehension at this high level of abstraction is based on many aspects of the message as well as on the participants' prior knowledge on the particular subject.

Although beyond the scope of this paper, it has to be mentioned that the transcriptions of these lectures show differences in how the subject matter was discussed in them. Lecturer in Lecture 21 was able to narrate and create a story rather than just stating facts. This lecturer also used many interactional features during lecturing to make the audience think about the subject: questions, repetition and directives[3] helped in that.

[3] statements such as "You have to remember!"

3 CONCLUSIONS

3.1 Research questions – answers?

As the results shown above indicate, lecture comprehension is dependent on other issues than English skills. The questions this paper set out to explore: whether 1) the lecturer's English competency is a key to students' comprehension and 2) there is a link between student's English competency and their comprehension of these lectures, thus have to be answered simply with "no" to both of them.

Nevertheless, it would be worth a further study to see what makes students evaluate their own English skills as "poor" or "fair" when they are using their English to study highly complex issues at a highly abstract level. What makes students' language identity [19] to be lower than what it actually is and is there a way to improve that self-image regarding English skills?

Another question is, whether lecturing should still be part of university studies. Similar aspects that influence lecture comprehension, however, are in effect also in any on-line materials, even when technology is called on to solve these issues.

Further studies on various aspects of comprehension and on English in Academia are needed as the way universities operate is constantly changing. Despite these changes, lectures have remained almost identical throughout decades – should they be modified somehow?

Appendix 1: Questionnaire

Please circle the correct alternative or write your answer in the space reserved for it.

1. I am 1 Male 2 Female
2. I was born (year) ____________
3. My native language is 1 Finnish 2 Swedish 3 Other, specify ____________

Please circle the most appropriate alternative. One response per question.

4. I speak English
   1 Daily
   2 Weekly
   3 Sometimes
   4 Hardly ever
5. I acquired English
   1 At school (general studies in native language)
   2 In an English-speaking country
   3 In a school where teaching was in English (with native language surroundings)
   4 Elsewhere, specify ____________
6. The level of my English skills in my opinion is
   1 Excellent
   2 Good
   3 Fair
   4 Poor

The following questions pertain to the lecture you just attended.
Please circle the alternative corresponding to your opinion.

		Agree	Somewhat agree	Somewhat disagree	Disagree
7.	I understood the contents of the lecture well.	1	2	3	4
8.	I did not understand the main contents of the lecture.	1	2	3	4
9.	Most of the lecture remained unclear to me.	1	2	3	4
10.	The atmosphere during the lecture was relaxed.	1	2	3	4
11.	The atmosphere during the lecture encouraged to question and to discuss the topic.	1	2	3	4
12.	I would have understood the lecture better in my native language.	1	2	3	4
13.	The topic of the lecture was so challenging that the language used would have not influenced my understanding of the lecture.	1	2	3	4
14.	The contents of the lecture were presented logically.	1	2	3	4
15.	It was easy to follow the lecture.	1	2	3	4
16.	The contents of the lecture remained secondary since I concentrated on the language so much.	1	2	3	4
17.	It was difficult to follow the lecture, but it had little or nothing to do with the language used.	1	2	3	4
18.	I felt uneasy for the lecturer while he/she lectured in English.	1	2	3	4

19.	I would prefer a native-speaker of English as a lecturer.	1	2	3	4

The following questions pertain to the lecturer's English skills.
Please circle the alternative(s) corresponding to your opinion.

20. The lecturer's language skills in my opinion are
    1 Excellent
    2 Good
    3 Fair
    4 Poor

21. The lecturer's language skills lack in
    1 Vocabulary
    2 Fluency
    3 Intonation (=melody of speech)
    4 Pronouncing single sounds
    5 Other, specify ___________________

ABSTRACT

University engineering faculties, professional engineering institutions and industry increasingly recognize that higher education should support students to develop key professional skills such as critical thinking and communication skills. This paper examines three activities aimed at teaching these skills, i.e. practical open-ended group activities; discussion with experts or as experts; and peer assessment. These methods were assessed in terms of student and staff opinions, but also practicality. Our research indicates that it is beneficial to integrate and balance these three types of activities within engineering degrees as they complement each other. Our findings and conclusions can be applicable to any engineering degree, whether the aim is to incorporate the teaching of these skills in a small activity within a module or a full programme of studies.

Keywords: critical thinking, engineering skills, peer assessment, research-based education.

INTRODUCTION

Engineering employers expect graduates to have a good knowledge of their field of study, as well as workplace skills such as critical thinking and communication skills [1,2]. Universities and professional engineering institutions increasingly recognize this need and incorporate the development and assessment of professional skills within their accredited curricula [3-6]. In general, practitioners acknowledge that these skills must be built over time, and therefore must be integrated throughout the programme of study. Different methods are used in the literature. This paper focuses on 3 generic overarching teaching methods, i.e. (i) open-ended practical activities and research based education, (ii) discussions with a range of experts and sectors, and (iii) critically analysing other students' work with peer assessment.

Open-ended practical activities and research based education provide students with "real-life working scenarios" where they apply and reinforce their technical knowledge, critical thinking and problem solving skills, as well as communication and team work. Employers are looking for graduates with this type of experience [2]. Students often find these activities challenging but often engage and learn with them.

Engineering students benefit from interacting with a range of audiences and experts, preparing them to communicate effectively in a range of roles relevant to industry, such as speaking with clients, experts, peers, etc. [1,2]. Furthermore, dialog with experts within and beyond academia challenge the students and supports their critical thinking development; while taking the expert role and engaging with less technical audiences -e.g. peers and junior students- develops their confidence and knowledge further [7].

Finally, peer assessment is increasingly applied in higher education because it enhances students' learning and development of critical skills [8,9] among other benefits [10,11]. However, there are concerns that students may not engage with peer marking [9,12] and may not trust peers to make fair judgements [12]. This can be mitigated by using the 360-degrees peer-assessment method (360PA) where students are assessed in part on the quality of feedback that they provide [13]. The use of peer assessment gives the students an opportunity to learn how to express feedback in a constructive and tactful way.

This paper describes and compares these three different educational activities to foster the development of critical thinking and communication skills. Evidence was obtained from teacher observations, discussion with teachers and student, and anonymous questionnaires filled out by students. Some examples of implementation and final recommendations to practitioners are provided.

1 PROJECT METHOD

1.1 Overview of activities incorporated within the programme

A range of "non-traditional" activities were incorporated within the BEng Biomedical Engineering programme (BME) (https://goo.gl/pfMTPa), part of the Integrated Engineering Program at UCL, UK. These complement traditional lectures, tutorial sessions, and traditional practical sessions often incorporated within modules where students carry out a set of defined instructions, e.g. an experiment, or certain routines in a piece of software. We investigate activities grouped into three general categories:

(A) Open-ended group activities: These are long practical activities where students are presented with a problem that they need to solve, or a research question that they need to investigate, but are given freedom in what the end-product should be or how to reach it, hence 'open-ended'.

We examine various instances of these open-ended group activities: (i) six so-called 'scenarios', which are one intensive full week activity covering a range of topics such as programming, electronics, mechanics, design, etc; (ii) research activities, typically spanning up to a term, where each group defines and solves its own research question, e.g. first year students investigate the mechanical properties of a material using the Instron E3000 [14], and present their results via poster in a conference-type setting; (iii) large design group project in the 3rd year.

(B) Discussion with experts or as experts: Meaningful learning requires that students are not passive receivers of information. Academic discussion with lecturers is a common practice in Higher Education and an excellent way of challenging students, widening and reinforcing their knowledge. Additional approaches investigated in this paper, are: (i) frequent exposure of students to non-academic experts, e.g. from industry or the health system including visit and shadowing clinicians at hospitals, and patients; (ii) students present and discuss their results to a range of experts in the field as part of the assessment; (iii) students are encouraged to engage with younger students and act as experts, e.g. supporting the teaching in a given practical, or discussing and giving formative feedback to 1st year students.

(C) Peer assessment (PA): PA is used in many modules across the degree, in a range of assignments such as reports of experimental work, video, a section of the final year project dissertation, presentations, and mathematical assignments.

1.2 Assessment of impact by students

Third year students were invited to complete an anonymous questionnaire. This questionnaire looks at how confident students are with respect to 4 specific skills, defined as S1 to S4 below, if they developed such skills since the start of their degree, and how the types of activity A, B and C (as defined in section 1.1) contributed to such development. All questions have a 5-point scale. Student's quotes are also provided. The skills investigated were:

- S1: Critical thinking
- S2: Communication with a range of audiences and different situations
- S3: Critically analyse someone else's work
- S4: Constructing feedback for peers or junior students.

1.3 Assessment of impact by staff

Similarly, interviews were conducted with members of staff to investigate the effect of activities A, B, C on the development of students' S1-S4 skills. Those staff members selected had contact with the students at different years during their degree. They were asked the following questions:

- Since the students started their degree, have you observed an improvement in their abilities with regard to S1, S2, S3 and S4? :

- If so, how did you observe these changes?
- What do you think has caused these changes?
- Have students changed their approach to scenarios?

1.4 Other factors

Also considered in the assessment is staff time and resources needed.

2 RESULTS

Students' feedback via questionnaires is presented in *Table 1*. A sample of students and staff point of view on these three activities is given in *Table 2* and *3* respectively.

Table 1. Third year students' responses to questionnaire (N=9, 90% of the class). Scale: 1- not at all, 2- not very, 3- fairly, 4- significantly, 5-very. Mean (SD)

	S1	S2	S3	S4
Current confidence in your ability?	3.9 (0.7)	3.9 (0.7)	3.7 (0.5)	3.9 (0.6)
Has it developed during your degree?	**4.4 (0.7)**	**4.1 (1.0)**	**4.2 (0.7)**	**4.1 (0.8)**
Has this type of activity helped you to develop it? (A) Open-ended group activities	**4.1 (1.1)**	**4.7 (0.5)**	3.7 (1.1)	**4.0 (0.7)**
(B) Discussion with experts or as experts	**4.4 (0.5)**	**4.3 (0.9)**	3.2 (1.3)	3.7 (0.9)
(C) Peer dialog and peer assessment	3.1 (1.3)	3.0 (1.1)	**4.0 (0.7)**	**4.0 (0.7)**

Table 2. Quotes from students (representative sample)

Student 1: *"Open ended activities have helped me improve my skills in communicating with team members and motivating each other to work well together to produce a good piece of work, towards a strict deadline. It's really helpful as it helps you understand what it's like to work in a team environment, especially for working in companies in the future.* *Discussion with experts helped me to improve my communication skills also, especially learning to be empathetic towards patients and what examiners want.* *Peer assessment helped me learn how to critically analyse someone else's work and ensure I give good feedback, as well at utilising the feedback I was given."*
Student 2: *"Discussion with experts: Good for constructing feedback as you learn the opinion of people with experience in a particular area, and you can apply this to your feedback for others. […]* *PA: Gives you more time to think about how to word your feedback, but quite frustrating if those who are giving you feedback do not put effort into it."*
Student 3: *"Being pushed to engage in the activities [A, B, C] meant there was a need to refine my skills in these areas."*
Student 4: *"[…] I think my critical thinking was developed most with the expert discussions as they would ask questions that make you think deeper about the topic, which I found challenging but good.[…]"*
Student 5: *"Open-ended group activities such as scenarios have greatly improved my critical thinking skills to solve new problems in a creative way. They have also improved my communication skills when working in a team with colleagues, lecturers and area experts. […]*

PA activities have improved my ability to construct feedback and shows you how other people think which can improve the way you critically think yourself.   *[Recommendations for the future] Continue to combine the talks with experts with the open-ended group activities. Peer assessment is helpful but is also time consuming […]. All these activities [A, B, C] are important and should be incorporated in the Biomedical degree."*

Table 3. Quotes from members of staff (representative sample)

EH, Laboratory Technician, supports students during practical activities and scenarios in years 1 to 3:   *"Yes, [I have observed an improvement on the students' abilities to S1 and S2].*   *S1: Students were made to think critically of their strategy in Scenario 2. [At the end] the students were asked to contribute one thing they had learnt […], some students were incredibly reflective realising their downfalls in planning at the beginning led to a poorly constructed investigation.*   *S2: Throughout scenarios students have needed to present their work to scenario leaders and experts, […] work as teams and communicate their ideas effectively. I have seen students greatly improve their ability to work in a team; some students start the first year scenarios afraid to speak their opinions to their team mates and are more confident in doing so by the scenarios in the second year.*   *[In] scenario 6, students get to experience contact with a 'patient' to test their device, this gives them chance to learn a vital skill in communicating at a completely different level to the common student- teacher interactions […].*   *In general: For some students failure has been the predecessor for change, learning from mistakes of previous scenarios.[…] By the second year students become much more familiar with the concept of scenarios and how to deal with them, they are happier with the freedom to plan and construct their own ideas. They do not ask for help as much, they come up with ideas within their groups and do not need constant affirmation."*
JG, Principal Teaching Fellow, lecturer in year 1 and lead of 2 scenarios: *"S1: It's difficult to say as I see just a snapshot of them. However I believe that the students' critical thinking improves during the week of the [3rd] scenario when they have to actively problem solve in order to get to the end point.*   *S2: Communication definitely improves throughout. First year students are usually quite nervous about presenting, but by the time they get to the [5th] scenario, they are almost all confident about presenting to what is actually quite a scary audience.*   *S3: Again, I've not seen the students analyse much of other's work – just really in Dragons den. This year, a couple of groups were able to comment on and consider whether or not they actually believed that the technologies given to them would be good in the market place. It takes a certain amount of confidence to speak up when presented with an academics' research work.*   *S4: I've not had the opportunity to see this in action.*   *In general: Giving them opportunities to attempt all these skills regularly, combined with a mixture of feedback and constructive praise [is what has caused this development on the students]."*

3 DISCUSSION

Engineering students and staff (including the authors of this paper) believe in general that the types of activities under study (A, B, C) did help to develop critical thinking and communication skills (S1-S4) of engineering students. A comparison between the 3 types of proposed activities is summarized in *Table 4*, and discussed below.

Type A activity, i.e. open-ended practical activities, seems to give the engineering students the chance to use - and the need to develop - the full range of skills (votes range 3.7-4.7/5) in general, and are recommended by staff for the training/learning they provide. According to the student questionnaire, S3 (critically analyse someone else's work) is perhaps the skill accomplished to the least degree with this activity, demonstrating that although students are working and assessed in groups, they are still not ready/inclined to analyse and criticize the work of their peers. But overall, the students enjoy and appreciate open-ended group activities. For instance, during one open-end research activity the 1st year students (N=23) claimed that they learnt a lot (mean vote = 3.8/4), and that it was a valuable learning experience towards their future (mean vote = 4.0/4). However, setting up, resourcing and running this type of activities can be highly time-consuming and costly.

Type B activity, i.e. discussion with or as experts, is very popular among students, getting a high mean score for S1 (4.4/5) and S2 (4.3/5). Students learn how to critically analyze and interpret information by discussing with experts (lecturers, researchers, industry, medical doctors), and learn to communicate with different audiences (including non-technical people e.g. patients). Part of this is done within classes and support sessions, which it is the least time-consuming and most economical option. However it is also good for the students to have the chance to share their thoughts with experts while working on engineering (open-ended) projects. These personal discussions are of high value as the student has a good understanding of the project at hand, allowing the questions/discussions to be deeper. If organized into timetabled sessions, these one-to-one discussions are feasible. However, the total number of staff hours increases with the class size.

Type C activity, i.e. peer dialog and peer assessment, seem to address the development of skills S3 and S4 according to the students, with scores of 4.0/5 in both cases. Many students see and comment on the benefits of this activity; however some are still skeptical and might not engage with it as much as they should because they consider it as something extra rather than part of the assignment. The use of the *360 degrees peer assessment method* partially solves this problem, while allowing staff to measure and assess the ability of students to construct feedback. It requires the students to critically analyze the work of their peers and engage with the feedback received – both of which they might not do otherwise even if working in groups! This type of activity is the least sensitive to class size, in fact allowing a large class to get feedback on their work in a relative small amount of time with minimal staff involvement and resources. Staff using this 360PA method thought that the feedback provided by the students was thoughtful, of good quality, and more extensive than that provided by staff [15]. Activities type B and C seem to be complementary to one another.

By the end of the third year of the programme, students were still not quite confident of their critical thinking and communication skills (S1-S4) with scores between 3.7-3.9/5. This is surprising, considering that activities (A, B, C) have been integrated across the programme in part with those aims, but reinforces the need to support the students in the developing of these skills as to be ready for their professional lives. However, it seems that the proposed activities work, with students acknowledging that they have significantly developed skills S1-S4 during their degree (average ranging

4.1-4.4/5). Students' preference and perceived benefits among these activities vary, further supporting that they are used in combination.

Table 4. Comparison of the proposed types of activities

Activity type	Students	Staff	Resources
(A) Open-ended group activities	High engaging, significantly develops skills S1, S2 and S4.	Develops S1 & S2, might help S3-S4 but no evidence. Very useful as training for engineering.	Highly demanding: space, equipment, staff-time for preparation and support
(B) Discussion with experts or as experts	Very useful for S1 and S2	Can be more easily incorporated in different parts of a module. Useful. Students might engage differently.	Staff time: medium No cost or lab requirements.
(C) Peer dialog and peer assessment	Significantly useful for S3 and S4. Not all students like it.	S3 and S4 can be assessed. Prompt and good quality feedback, more detailed than staff can provide.	Staff time: low No cost or lab requirements. Easily scalable with class size.

4 CONCLUSION

This research looked at 3 generic types of activities, and seem to be in agreement with other studies in the literature that claim the benefits of using active learning methods such as project-based learning [3, 5] (type of activity A) and outfacing assessment to High School students [6] (a form of activity B). It also covers the evaluation of peer assessment (type of activity C) that was identified by Llorens [3] as something that had to be investigated.

Our practice suggests that it is beneficial to integrate in the programme a range of practical open-ended and research-based activities, dialog with a variety of experts and sectors, and the use of peer assessment for various elements. A balance between these options is desirable, as the first two are demanding in terms of staff-time and resources, while peer assessment can be more scalable. The combination is able to cover the development of the studied skills, i.e. critical thinking and communication skills. Our approach is relevant to teaching critical skills, either in a small activity within a module or a full programme of studies.

This research should continue to proof its reliability, involving larger classes and perhaps looking at student and staff perception after the 1st and 2nd year of the degree.

5 ACKNOWLEDGMENTS

The authors would like to thank to the students and staff members (Miss Eve Hatten, and Dr Jennifer Griffiths) who provided feedback and quotes for this paper.

ABSTRACT

Nowadays it is generally recognized that in order to be an effective software engineer one requires skills for performing in a team. Therefore, research on team working skills in software engineering education has been gaining more attention. Most of the studies have focused on how a certain learning-teaching approach impacts team work. Despite these efforts, human aspects haven't had the attention they deserve to better educate software engineering students. This work shows the results of a pilot study in software engineering education related to the influence of cohesion on team performance behaviors. The relation between these variables is looked at through the lens of an IMOI (Input Mediator Output Input) model. Team cohesion acts as a *mediator* to improve team performance behavior *outputs*, whereas the intervention on cohesion is seen as the *input.* After some appropriate training on team working skills, students have to establish team rules on communication and conflict management. We assume that this will improve the team cohesion, and lead to more effective team performance behaviors. Improvement of the rules (*input* again) is then based on tracking the behaviors of individual contributions to the team work. The study presented here was performed in the software engineering program at University of Holguin in Cuba.

Conference Key Areas: Engineering Education Research, Engineering Skills, Curriculum Development

Keywords: team work, software engineering education, cohesion, team performance behavior

INTRODUCTION

Engineering education is critical for the development of industry and hence of society in general in any country. Preparing engineers for the future, [1] includes training them on technical and professional skills closely related to team work, like project management, leadership and communication skills. The ability to work as an effective member of a development team is a primary goal of engineering education [2] and is also included in the ABET students' learning outcomes criteria for accrediting computer programs [3].

Team work is especially important for software engineers due to the complex socio-technical nature of their profession, broadly recognized by authors like [4]–[7]. IEEE defines software engineering as "the application of a systematic, disciplined, quantifiable approach to the development, operation, and maintenance of software" [8]. Software engineering needs engineers able to play different roles during several tasks, coordinating efforts to achieve coherence in different phases of software engineering process.

Several aspects of team working in software engineering education have been studied. In particular, some authors such as [9], [10] focus on studying team performance. Several measurement instruments have been used; they all put more emphasis on the process results rather than on the behaviors that allow software engineers to obtain team objectives. Cohesion is considered as one of the most important factors that influence software teams. It has been found important for team effectiveness [11], [12], motivation [13], productivity [14], team collaboration [15] and for agile practices [16], [17]. However, cohesion has been scarcely studied in software engineering education and there is not empirical evidence on the relationship with team performance behaviors.

The remainder of this paper is structured as follows: Section 1 describes the framework proposed to guide the study. Section 2 refers to the context of the study, the method of intervention and the results of a pilot experiment. Section 3 concludes the paper.

1 IMOI FRAMEWORK ADAPTED TO THE STUDY

Factors that affect team work are very well known and largely studied in organizational settings. In a review of ten years of research on team effectiveness, [18] stated that all the affecting factors of team work can be studied using an IMOI model. This model describes how all the factors can be related with inputs, mediators or outcomes of the team work process. The authors state that cohesion acts as a mediator whereas team performance is related with the outcomes. Another meta-analysis done by [19] found that cohesion is strongly correlated with team performance when the latter is measured as behaviors. Identifying the input factors for team work in higher education, [20] identified team rules, task agreement, rules agreement and establishment as the most important ones. Taking into account that software engineering methodologies are clearer on task and roles, this study focuses on rules.

Following these statements the IMOI model was adapted to the pilot case in software engineering education at study, as shown in Figure 1.

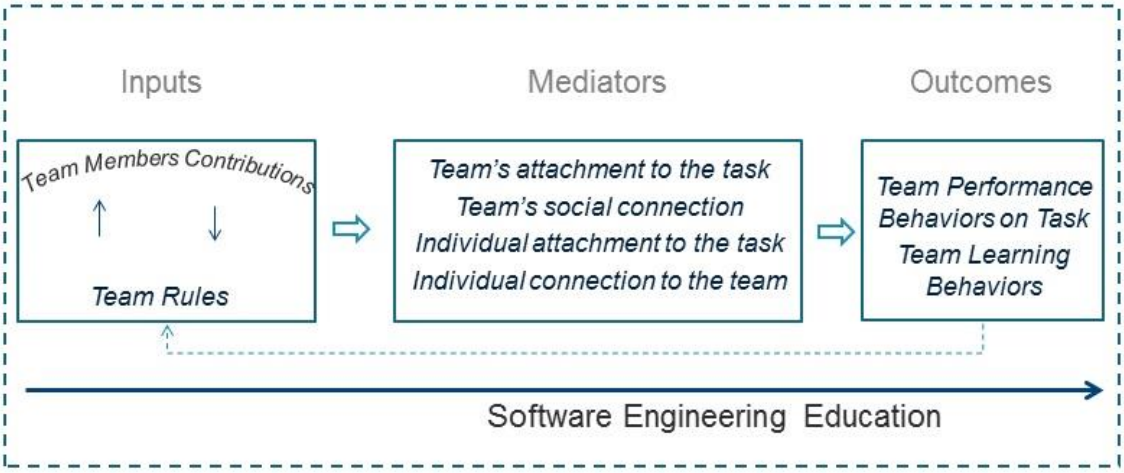

Fig. 1. Model IMOI used in the study

Team rules were established regarding communication and conflicts management. Communication has been postulated important to cohesion by authors such as [21]. [22] stated that communication difficulties decrease cohesion and increase conflicts. Team rules, as input factor, are updated based on team member evaluation of their individual contributions to the team work. Team members' contributions were indeed found highly correlated with cohesion by [23].

The factor team cohesion is considered as the mediator in the model. For the purpose of this study we go back to the conceptualization of [24], applied by [25] to software engineering students. In their vision cohesion can be thought of in two very different ways: the social attachment within the team and the team's connection to the project itself; and at two levels of granularity: at the individual level and for the team as a whole.

The output in the model is established by team performance seen as behaviors related to performance on task and team learning. Team performance is usually measured with indicators for effectiveness and efficiency. However, [18], [19] differentiated between performance behaviors and performance outcomes. According to [18] team performance behaviors are actions relevant to achieving goals, whereas outcomes are the consequences or results of performance behaviors. In this study are observed team learning behaviors as the 'activities carried out by team members through which a team obtains and processes data that allow it to adapt and improve' [26]. Performance on task is assessed according with the degree in which the team satisfies client needs and expectations.

2 STUDY REPORT

Software engineering is one of the most important discipline in the Informatics Engineering bachelor program at University of Holguin. The program taught includes team work applying methodologies while solving real life problems. The students in the study were in the third year of the program, and we observed them in two courses: Software Engineering I and Software Engineering Management. In these courses students learn how to apply the Iconix methodology and manage their software projects working in teams. During three months they had to perform the two first phases of Iconix methodology ‘a requirement analysis’ and develop a ‘preliminary analysis and design’. The rest of the Iconix phases will be studied in a next semester. They also have to organize their team work and plan and track their projects. A total of 34 students were studied. They were performing in 7 teams of 3-6 members.

As can be seen in Figure 2, the intervention by the teacher on the teams consisted of three phases over a period of three months. Teams were formed in the first week of the semester by a self-selection method. At that time an individual diagnosis on team working skills was done with a Team Knowledge Test (TKT) questionnaire, used by [27] to survey software engineering students. After three weeks performing, team cohesion and performance behaviors were measured. Questionnaires proposed by [24] and [26] were used, slightly adapted to educational settings.

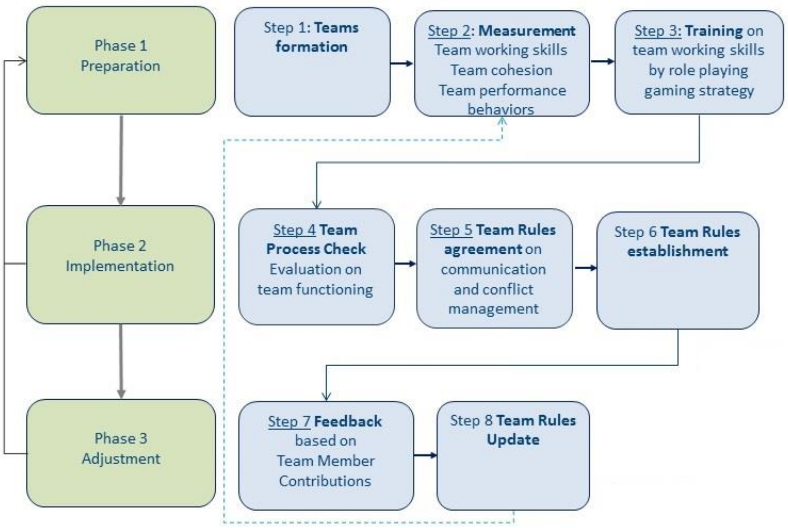

Fig. 2. Method of intervention

The training on team working skills was based on a role playing strategy and it was focussing on communication and conflict management. In order to play different roles, students were asked to fill in the Belbin questionnaire, which allows identifying team roles [28]. Belbin team roles are based on behaviors that individuals adopt when participating in a team. The awareness of those roles could help amongst others, to foster mutual trust and understanding and to build productive workplace relationships. Software engineering roles like analyst, programmer, tester and client were used. Conflict situations were simulated by providing software artefacts and project documents such as a project planning, a list of requirements and several check lists. Student had to solve those situations playing different roles as a software engineer.

After one month working together, students evaluated the functioning of their teams. Using that information and based on lessons learnt from the team working training and their individual diagnosis, they were asked to agree on team rules. The rules were about communication and conflicts management. Some examples of the rules they agreed were: *don’t discuss personal conflicts at work, appoint mediators to manage conflicts, discuss disagreements openly, put all information visible for all,* *listen to all opinions without interruptions, let everybody express their opinions, use blackboard to remember meetings, keep communication frequently with clients,...*

Students were then continuing their team work for one month under these team rules. After that they were asked to self- and peer-evaluate team member contributions. This information assisted as a feedback to update the rules. Team member contributions were evaluated on five areas, according to three levels of team performance behaviors, using the questionnaire proposed by [23]. The areas include contributing to the team's work, interacting with team mates, keeping the team on track, expecting quality and having relevant Knowledge, Skills, and Abilities (KSAs).

At the end of the third month the study was concluded and the same variables as in Step 2 of Phase 1 of the intervention were measured again. A 5-point scale, from "*strongly disagree*" to "*strong agree*", was used. Table 1 shows the overall values for each variable, averaged over the seven teams, before (i.e. three weeks in the study) and after the intervention (i.e. at the end of the study). In the third column we present the delta, and in the last column the p-value after perform a t-student test (using SPSS 20.0).

Table 1. Variables values before/ after the intervention

Variables	$\dot{x}_{Before}$	$\dot{x}_{After}$	$\dot{x}_{Difference}$	**p-value**
Cohesion	3,06	4,09	1,03	0.000
Team Performance Behaviors on Task	3,18	3,96	0,77	0.000
Team Learning	3,09	3,98	0,89	0.000
Team Performance Behaviors	3,14	3,99	0,86	0.000

As can be seen, the overall value all variables had a substantial increment after the intervention. However, during the study it was observed that changes in levels of the two team cohesion dimensions, social attachment within the team and the team's connection to the project itself, didn't show a similar change. It seems that the second aspect had more impact on the overall result for cohesion than the first one. For that reason, further analysis of these different dimensions of team cohesion is needed at the individual level of granularity and for the team as a whole.

3 CONCLUSIONS AND FUTURE WORK

The pilot study presented here shows that team rules on communication and conflict management improve team cohesion, which leads to more effective team performance behaviors. The individual diagnosis and subsequent training on team working skills using a role playing strategy, together with team functioning evaluation, provided the basis to the team rules agreement. The feedback obtained by team member's contribution assessment after working under this agreement enabled students' recognition of changes needed on the rules and allowed them to update their team rules agreement. Future work will explore in more detail how the intervention as described in this paper affects the different dimensions of team cohesion and how they impact the team performance behaviors.

ABSTRACT

Abstract

Given the escalating demands for “work-ready” undergraduates plus the heavy workload of engineering faculty and students, adding effective communications instruction to the engineering curriculum is a significant challenge. In response to that challenge, the Sibley School of Mechanical and Aerospace Engineering (MAE) and the Engineering Communications Program (ECP) at Cornell University have begun to develop a new communications curriculum. The new curriculum has two components: 1) partnering a sophomore-level mechanical engineering course teaching mechanical design principles with an engineering communications course; and 2) integrating focused communication units in select junior and senior level MAE courses. Our aim is twofold. First, we hope that partnering these two courses will offer a more impactful and expertise appropriate way to deliver communications instruction. Second, we also hope that implementing a coordinated communication-across-the-curriculum (CxC) effort will better meet the needs of students, faculty, the college and industry.

This new (and still developing) curriculum, named the “MAE/ECP Engineering Communications Initiative,” is a collaborative and cooperative enterprise encouraging the development of students' communicative self-efficacy (CSE) across a range of engineering communicative genres. Four foundational concepts are our benchmarks: communication as social action, the importance of context, communicative design, and engineering identity. Both the partnering and coordinated communications modules are continually assessed through a multi-year, mixed-methods research program. The first years’ quantitative findings for the communications course show noteworthy increases in CSE, with the second year’s quantitative findings reportable by conference time.

Conference Key Areas: Engineering Skills, Curriculum Development, Engineering Communication

Keywords: Engineering Communication, Communicative Self-Efficacy, Curricular Integration and Assessment, Educational Research

Introduction

Engineering communication is ubiquitous in the lives of professional engineers and engineering students alike. Recent surveys indicate that engineers spend between 40 and 60 percent (and more) of their workday engaged in communicative activities [1-4], and anecdotal reports suggest an even higher percentage. And while many admit that effective communication is a core skill set of any adept engineer, too frequently curricula siphon off communication skills into a less-than category, too often called "soft skills," hinting (sometimes declaring) that other engineering skills are harder and more valued.

We challenge that thinking at its very core in our work teaching engineering communication inside a US college of engineering. Almost all job postings for entry-level engineers require "excellent communication skills, both written and verbal." Beyond entry-level jobs, employers assume good communication skills are in place, and people who rise quickly through the management ranks tell us that it is their communication skills that make them stand out. As well, experienced engineers or engineering managers often highlight not only the relevance of communication, but also the diverse range of communicative actions that they must perform in order to get work done. [5].

The challenge of infusing communication skills into technical-leaning courses in any engineering curriculum can be a difficult proposition. Most engineering curricula are already heavily burdened with core courses and specialized, field-specific content; so adding direct and recurring communications instruction to an engineering curriculum represents a significant challenge.

Responding to that challenge, some engineering programs are experimenting with creative and engaging ways to develop communication skills. One such experiment is the fostering and use of teaching "partnerships" that tap into the expertise appropriate skills of the technical specialist/engineering instructor and the technical communication instructor respectively. With these kinds of positive partnerships, course content can realign towards "socially situated [technical ***and*** professional] practice" [6], while also possibly reducing workload for that engineering instructor. The Sibley School of Mechanical and Aerospace Engineering (MAE) and the Engineering Communications Program (ECP) in the College of Engineering at Cornell University are actively facilitating the formation of such a partnership.

We discuss our theoretical and pedagogical underpinnings, teaching approach, and quantitatively report the outcomes of our first year teaching the partnered communications course. By conference time, we will have data to share from our second year.

1 Background: The MAE/ECP Engineering Communications Initiative

The Sibley School of Mechanical and Aerospace Engineering (MAE) currently requires its majors fulfill a college mandated technical communications requirement via its senior level (year 4) capstone lab course. The communication component relies primarily on lab reports and designing visuals. The engineering instructors do successfully empower students to produce good reports and well-designed visuals. However, departmental descriptive surveys, e.g., those involving students, alumni, industry representatives, suggested that MAE needed to do something more to prepare students for workplace and research communication needs. Indeed, MAE openly wondered if there might be a better way.

In search of this better way, the MAE department, in concert with the college's Engineering Communications Program (ECP), identified a number of important needs. Communication instruction should:

- begin sooner in the MAE curriculum; the aim is a coordinated and constant development of communication skills across the curriculum;
- cover multiple modes – written, oral, visual, electronic (WOVE); the intent is to encourage the transfer of communication skills across technical and professional endeavors;
- empower students to experience the integration of technical and professional practice and develop skills such as iterative revision, peer response; they should be ready to learn to learn how and to teach each other;
- build on single set of theoretically established and foundational concepts:
    - **Communicative Practice:** When we communicate, we perform specific social actions. All communication has one or more purposes.
    - **Communicative Context:** Communicative practice cannot be separated from context nor the context from practice.
    - **Communicative Design:** Communication is all about the particulars of design or structure and organization.
    - **Communicative Identity:** Communication creates identity, not only the identity of the one initiating communicative interaction, but also the identity or identities the one or ones being communicated with.

Rather quickly it became clear that to be able to realize these needs, MAE and ECP together needed to create a new MAE communications curriculum and devise a research program for assessment. The core design of the effort is this: one dedicated, engineering communications partnered with a (preferably design) MAE course at the sophomore level; integrated, focused communication units inside select junior and senior courses.

The sophomore communications course, ENGRC 2250, launched in spring 2016, had 20 self-selecting MAE undergraduates enrolled. Quantitative *and* qualitative research was done in parallel. We framed our research question thus:

> *How well can we facilitate the development of communicative self-efficacy (CSE)?*
> Or…more closely drawn:
> *How well can we facilitate in MAE undergraduate engineering students the development of communicative self-efficacy (CSE) through ENGRC 2250 and then foster its continuing development through select junior (level 3) and senior (level 4) courses in the MAE curriculum in a way that transfers to and enables proficient technical and professional communicative practice?*

We propose that the MAE/ECP Engineering Communications Initiative innovates in a number of ways:

1. It offers both a horizontal and vertical curriculum that is theoretically consistent for providing communication instruction. It potentially offers a model for other schools and colleges of engineering.
2. It anticipates and enables learning to learn how in post-graduate technical and professional communication by providing students experience applying those

foundational concepts within different contexts, using multiple modalities (WOVE) and across many genres.

3. It proposes a model program for near- and long-term assessment through locally-situated and emergent educational research.

2 Research mandate, self-efficacy, and methods

Briefly put, we designed our research protocols pragmatically. We needed to study the impact of communication instruction upon undergraduate students in an engineering curriculum. After much work, we formulated an explanatory, sequential mixed methods design, i.e., survey along with classroom participant observation, interviews, and portfolios. All data collection was institutionally IRB approved.

We built our survey around discovering reports of student communicative self-efficacy (CSE). In choosing to do so, we participate in a well-established practice in engineering education. Self-efficacy (SE) measurements capture how well subjects (in this case, undergraduate students) rate themselves as having positive behaviors; consequently, positive behaviors translate into higher-performing practices. In ASEE (American Society for Engineering Education) Proceedings alone, there are over 1400 references to self-efficacy in student engineering practice. The *European Journal of Engineering Education* boasts 70+ articles about self-efficacy in engineering students in the last decade alone. Self-efficacy is an established and useful construct based originally in Social Cognitive Theory [9]. It "refers to beliefs in one's capabilities to organize and execute those courses of action required to produce given attainments" [10], or a "person's awareness of their ability to accomplish a goal" [11]. As a research construct, SE has proven to be a powerful predictor of achievement in general areas– general learning, academic achievement, retention, mathematics – and more specific areas – computing [11], engineering design [12], engineering modeling [13], even tinkering [14] to list just a few. Implementing CSE requires development of a survey instrument, which, although not easy, allows us to generate quantifiable results and to avoid (quite frankly) those prohibitively time- and labor-intensive alternatives for assessing communicative performance. As a result, and along with other possible contributions, our research has the opportunity to offer a model for the development of other similarly focused assessment instruments.

MAE students enrolled in ENGRC 2250 took two identical surveys—at the start and end of term. Also, and for the purposes of comparison, the survey was distributed to other sophomore, junior and senior level students across the larger MAE curriculum at the start of the term. Details on method and data tables of results are at https://sites.coecis.cornell.edu/chec/ecp-research/.

3 WOVE: Actionable and socially constructed modes

WOVE is the acronym for the written, oral, visual and electronic modes of communication. It is an emerging research area for engineering education [5]. For our Initiative, specifically, we focused on the particular genres and those modes most important for undergraduate and sophomore level students enrolled in the MAE program.

WOVE elements do not exist in a vacuum [6]. Lab reports almost always include visuals: graphs, tables, charts, sketches. Engineers and scientists might use LaTex coding to convey equations inside of email. Visuals include strong captions, which involves a specialized style of writing that helps readers decode the graphical input.

Oral presentations bring speech, visuals, writing, and performance together. In truth, it is hard to find engineering or scientific work that exists in just one mode. Indeed, even student project teams thrive in the multimodal milieu: speech, of course, but that communication also involves email exchanges, texts/texting, drawing, and more.

By creating ENGRC 2250, we devised work cycles that encouraged the students to develop facility with each of the isolated modes, but they were also developing facility to combine different modes into a single communicative genre given the modality's relative affordances or potentialities and constraints or challenges.

4 Brief overview of the teaching partnership

Students in the mechanical engineering course are required to design a wind/water pump from basic, inexpensive materials that can move a specific volume of water powered by wind, with constraints for cost, etc. Those pump projects are a stand-alone project; students work in teams and do not have to configure a pump system beyond materials, design, and the ability to move a certain amount of water in a given time in a lab setting.

In order to make the experience in the partnered communications course *more authentic* and to encourage *real mastery experiences* (the most significant factor in improving SE generally and CSE specifically), the pump design project became the cornerstone of a larger vision of the place of engineering in solving localized problems. ENGRC 2250 asked that students explore ways in which good engineering design is always contextualized, answering the needs of a set of specific set of circumstances that are economically, environmentally, socially, and politically bound. Halfway into the semester, students began intense work that focused on team dynamics, functionality, and workflow, followed quickly with the teams' proposals for their projects. Teams chose a community that was water-poor and placed their designed pumps in that site (in theory). Written proposals plus a presentation required that each team to identify its target community for pump placement and define the wind/water pump solution that could best fit localized need. In addition those student teams produced final reports and gave presentations based on those reports.

Providing a context for the wind/water pump was an essential step in the journey for students, moving from the classroom + lab to the "real world." As well as communicating their technical work on the pump mechanism developed in their mechanical engineering course, the communication project charged teams with the investigative tasks of identifying a community in need, contextualizing water access problems, exploring the history of the community and its water needs, and delving into the aspects (as best they could) that reflect the social justice challenges of engineering. As teaching partners, our motive was to have students experience, even on a small scale, the complex process of moving a technological invention out of the lab and into a demanding situation that was impacted by those opportunities and challenges that every professional engineer encounters. Along the way, we asked them to examine, reflect upon, write about, present, and explore the communication strategies and channels needed for strong work and project deployment.

5 Results of the quantitative survey regarding student communicative self-efficacy (CSE), start of semester

Herein, we provide a quick overview of our research results from the 2016 findings. Our extensive data set (Tables 1-14) is provided fully at https://sites.coecis.cornell.edu/chec/ecp-research/.

Perhaps the most important result, at least as it pertains to the quantitative study of CSE, is that the survey instrument that we designed is valid. We know that "validity is not [merely] a property of an instrument" [16], or the answer to the statistical question – does the survey actually measure what it is supposed to measure? Rather, it is revealed by whether or not the resulting scores provide a reasonable and useful representation the subject/topic under investigation. We assert that our data do provide such a representation both for how MAE undergraduates understand their ability to communicate for engineering work and how they understand that that ability develops.

So, what is that representation? Our survey results from the general undergraduate MAE student population shows that CSE increases both for individual survey items items and across the various modalities or WOVE as experience increases. That is, the mean scores of seniors exhibit higher CSE than juniors and juniors higher than sophomores. This increase suggests that students understand that their ability to communicate is a ***learned experience*** that increases with ***deepening disciplinary involvement***, ***advancing academic level*** and is enhanced through ***opportunities to practice***. However, the increase in CSE between the sophomore and junior levels is relatively trivial. The average improvement of the mean scores for individual items is 1.3 points and 1.7 for modalities respectively on a 100 pt. scale. Indeed, there is even some regression. And, the increase between junior and senior levels is modest: 7.5 for individual items and 7.2 for modalities. Knowing that for these undergraduate engineering students CSE does increase, albeit incrementally and not without regression, is important for two reasons. First, understanding that students do improve with disciplinary involvement and advancing level and through practice reinforces the value of each of these factors. Second, understanding that that improvement is limited suggests that there may be (indeed should be) a better way to enhance that improvement.

In comparison with the general MAE undergraduate population, the ENGRC 2250 students report a threefold improvement in CSE. And, since the time points for the baseline and the follow-up surveys are the beginning and the end of the term, we attribute that increase to their experience in the course. Specifically, the survey revealed increases in the mean CSE scores both for individual items, approximately 26, and across the various modalities or WOVE, also approximately 26. On the individual survey items, nearly 46% of all MAE students rate themselves as high, between 80 and 100 on the survey scale; while 81% percent of the students who completed the communications course rate themselves as high. For modalities, the percentages are similar: 44% for all MAE students and 84% for ENGRC 2250 students. The average mean CSE scores for all students at the end of the communications course is 90 for both individual items and modalities. This score becomes even more impressive when we note that only 23% of students in the baseline survey rate themselves as high. Finally, the average change between the minimum score on each of the items in the baseline and the minimum score on each of the items in the follow-up survey is 42 points. To highlight just one item: we asked students to rate their CSE as to whether they could, "give effective talks/presentations." At the start of the semester, the mean score was 55.4. At the end of the term, the same question provided a mean score of 91.7 again on a 100pt scale.

The data we collected (available at [redacted URL]) clearly reveals that changes in CSE are significant for students in the communications course. The single most important takeaway is that there is indeed ***a better way***! The only caveat is that our research-to-date is based on a small sample, and it will be important to replicate these patterns and their associated intensities in future distributions of the survey.

7 Conclusion and Next Steps

We piloted the partnering of two courses in an attempt to create a more impactful and expertise appropriate way to deliver communications instruction. And, assuming that CSE is a legitimate means to assess that more impactful and expertise appropriate way, we found that the partnered communications course dramatically increases undergraduate students' CSE scores. Moving forward, we are keen to learn if their CSE continues to grow, stabilize, or decrease. Using our validated survey tool, we will be able to track such findings.

To review, there are three direct outcomes from the quantitative study: 1) We have a valid instrument to measure CSE, 2) The general population of MAE students show minor improvements in CSE advancing through their senior year, and 3) Students who did take the partnered communications course show a threefold increase in CSE when compared with students who did not. Consequently, we feel safe asserting that direct and recurring instruction and possibly the mastery experiences that result from that instruction leads to significantly greater improvement in CSE. We also feel safe asserting that the curricular model that we have developed for enhancing students' communicative abilities has potential.

While our research is still very preliminary, there is also an important and emerging question that will merit continuing study. Because those students who have taken ENGRC 2250 are familiar with the foundational concepts related to communication, because they are strategic users of the modalities, across a range of contexts while assuming new communicative/professional identities, and finally, because they have high CSE — are ready to learn to learn how to communicate? Are ready to engage in those behaviors that transfer well into professional practice and lead to communicative success? We will rely on our qualitative data and continuing research to answer this question.

Currently, our plan is to continue to foster and expand our teaching partnerships with MAE faculty across the curriculum by offering communication units in select junior and senior level courses. The impact will all the more be strengthened if we can reinforce the idea that good, thoughtful communication is, as we claim, ***ubiquitous***. Working with the assumption that our approach to near- and long-term assessment can enable not only MAE but also other engineering schools and departments to offer concrete learning outcomes and produce actual data to support those outcomes, we will be continuing partnerships in the College and potentially in other departments, as well.

We believe that we have made a promising start toward planning and implementing an alternative communications curriculum that empowers students to be stronger communicators and therefore better representatives of the university and assets to their future employers. Of course, we move forward carefully and intentionally, as we are so early in the research process and pull from such a small sample size. Nevertheless, it is safe to suggest that the partnered ENGRC 2250 course resulted in *positive and trackable impacts about students' reported communicative self-efficacy (CSE) in engineering contexts while providing for those students a way to experience communication as an integral component of engineering work.*

ABSTRACT

This article aims to explore the self-perception of engineering students about their skills to innovate. We investigate what skills they need to innovate and to what extent they feel they are sufficiently well trained in their engineering school to work innovatively in their future career. Based on a recent literature revue, we point out the essential skills required to innovate. We applied a methodology of sequential exploratory approach including at the first phase a preliminary exploratory study and a quantitative online survey at the second phase. Our results indicate that open mindedness; objective outlook and creativity are perceived as the most important for innovation activities. Surprisingly, half of the surveyed engineering students declared that they feel not to be sufficiently well trained to innovate. We found for several soft skills such as creativity, objective outlook, critical thinking and open mindedness an important divergence between their training and their perceived importance. On the contrary, for hard skills like knowledge, technical expertise and experience our results show a particularly good convergence. Our results suggest that better integration of soft skills to innovate in the engineering curriculum would be beneficial.

Conference Key Areas: Engineering Skills

Keywords: Engineering skills, Innovation, Students' perception

INTRODUCTION

In our knowledge-based global society, the ability of industrial business organisations to innovate is an essential condition, if not the most important, of their survival on the globalised market. Consequently, they have to innovate continuously to retain their market shares and keep their place. In order to obtain sustainable competitive advantages and high performances, they have to be able not only to follow the market's global trend, but to be always one step ahead of their competitors. There is no doubt that their engineers' skills play a central role in innovation and value creation. Furthermore, they are considered as the main investment to develop a successful innovation strategy [1]. For this reason, industrial organisations have a strong interest to recruit young engineers adequately skilled to innovate.

For the younger generations of engineers, innovation skills have become more crucial for their employment and career prospects [2]. In a context of post-industrial society, there is a strong requirement for the engineering profession to innovate. In the case of innovation work, young graduate engineers need a solid technical background but also various non-technical skills. They have to be able to create not only technological innovation but products, services, processes, social or societal innovations. Given this larger scope of required innovation capacity, they need a new and larger set of skills.

Our research is based on engineering students' perception. Indeed, the study aims to answer the following questions:

1. What are the most important skills needed to innovate from an engineering student's point of view?
2. Do students feel they are sufficiently well-trained in their engineering school to innovate?
3. What skills do they feel they lack regarding their own curriculum?

In this article, we will explore the perception of engineering students if they feel adequately prepared or not to innovate in their future professional life. First, we will discuss about the needed skills to innovate based on a recent literature revue. Then, we will explain the applied methodologies for our research survey. In the next section, we will highlight significant results and their interpretations by outlining unexpected findings. To conclude, we are going to point out the limitations of our study and define future perspectives.

1 THEORICAL BACKGROUND

The increase in global market competition experienced by many employers forced higher education to adjust the academic training [3]. Consequently, engineering education had to adapt its curriculum by extending its composition to meet a more diverse range of skills than was formerly required. Thus, non-technical skills, also called soft skills, gradually entered the engineering training and became an essential component of engineering courses. Communication, relationship management, intercultural management and analytical capacities -among others- are included in these soft skills. As a whole, they are supposed to enhance the adaptability of future engineers in the ever-changing world that surrounds us. It impels graduate engineers to become pioneers of innovation and makes them more valuable on the labour market.

In his work, Passow [4] developed an ABET (Accreditation Board for Engineering and Technology) competencies ranking regarding their level of importance for professional practice from a perception of graduate engineering students. It shows that soft skills like the ability to work in a team, communication and ethics are perceived as being the most valuable competencies of the ABET program, before sciences. There are significant deviations between the technical and non-technical skills. This result is quite surprising regarding the fact that technical competencies are considered as the core competencies of engineering education. However, graduate engineering students evaluated these competencies as being less important in professional environments.

Innovation is a broad concept and there are many definitions for it in the literature. Between these definitions, the better-known is the definition by Oslo Manual [5] describing innovation as ‘the implementation of a new or significantly improved product (good or service), or process, a new marketing method, or a new organizational method in business practices, workplace organization or external relations’. This definition includes not only technical innovation but also different adaptations such as social, marketing, processing innovation etc. that require mainly non-technical skills for innovators. Especially for engineers, technical skills are really important to innovate but they have to complete these skills with a strong background of non-technical skills.

In recent years, there has been considerable interest in skills needed to innovate. In 1985, Quinn [6] wrote one of the earliest papers about the most common skills that most innovators possess. She identifies several personal attributes that she observed in many innovative small companies: problem-solving abilities, multiple approach attitude, flexibility and the ability to adapt themselves to low resources. Following this idea, it was suggested that skills required to innovate are indeed a real issue and that the need for specific-skilled employees is not limited to the R&D function anymore [7]. Recently, it was observed by Toner [8] that only 2.2% of innovative firms recruited scientific personnel for innovation and that the skills recruited by the highest proportion of innovating firms were general business (22.6%), information technology (18.2%) and marketing (16.7%). He also studied the most common barrier for a business organisation to innovate, where lack of skilled staff is ranked as the third barrier to innovation (27.2%) behind cost and market related barriers. The phenomenon implies furthermore that specific skills identified as innovation skills are very valuable, especially for future innovators that graduate engineering students should be.

Boyd [9] introduces an innovation competency model in the industry where the core competencies are: creativity including generating ideas, critical thinking, synthetizing and problem solving; enterprising including identifying problem, seeking improvement, and gathering information; integrating perspectives such as openness to ideas and collaborating; and managing change regrouping sensitivity to situations, and intelligent risk-taking. A conceptual model was then developed by Harrison [10] for exploring skills for innovators. The model features indicators that influence innovation as a competence: cognition, technical knowledge, managing change and creativity. This means that these indicators of an individual’s personality and abilities impact on that person’s capacity to work innovatively. The two authors have a different approach of skills to innovate; indeed, Harrison [10] underlines the influence of the individual’s character on the ability to innovate while Boyd [9] highlights the importance of possessing advanced specific skills.

All of the previously mentioned research papers studied a range of skills needed to innovate, however the alignment of these skills with the ones that graduate engineering students actually possess is not well-explored.

2 APPLIED METHODOLOGY

To complete the literature review, we applied a mixed methodological approach known as the sequential exploratory strategy [11]. It involves a first phase of qualitative data collection and analysis followed by a second phase of quantitative data collection and analysis. First of all, an exploratory qualitative study was led by interviewing experimented engineers in order to define the most appropriate skills to innovate. Secondly, a quantitative study was carried out to target innovation skills and the way they are perceived by engineering students.

Our preliminary qualitative study was initially conducted to design the online survey. Twelve professional engineers operating in a highly innovative working environment were interviewed. We have chosen these professional engineers with different professional profiles working in diverse industrial sectors in order to have the most heterogenous sample possible. The interviewees were asked to speak about innovation in a general sense. The discussions then continued towards the actual skills they consider essential to innovate. Each interview was recorded and then transcribed in order to facilitate the analysis of the corpus. This allowed us to outline eighteen skills related to engineers' ability to innovate.

The development of our quantitative study final structure was based on findings from the literature revue and the results of the twelve qualitative interviews. The aim of this quantitative survey was to evaluate the impact of the engineering curriculum on the students' innovation skills and to highlight the domains where engineering students feel they are lacking. We designed an online survey that was sent to 678 engineering students at master level specialised in various fields (e.g.: electronics, mechanics, computer sciences etc…) to ensure the heterogeneity of the sample. First, the respondents were asked to evaluate the level of importance of innovation for the practice of engineering profession using a five-point Likert scale. The survey was then divided into two sets of questions. The first part questioned the perceived importance of the skillsets and competencies necessary to innovate. In the second part, we asked the respondents if they felt they were well-trained or not in their curriculum. We finally asked the students to indicate their missing skills.

We gathered answers from 181 students from a top engineering course in France that makes an answering rate of 26.7%. A method of ranking comparison of the eighteen skills evaluated by the students was used to analyse the data of the quantitative study.

3 RESULTS

Our findings clearly confirm the importance of innovation activities perceived by engineering students for practicing their future profession. They evaluated the importance of innovation activities for engineers at 4.24 on a five-point Likert scale in our online survey. This value correlates with the findings of our qualitative study where engineers' innovation capacities were outlined as a critical resource for industrial and business organisations. It was unanimously expressed by the interviewed professional engineers that innovation capacity is considered today as basic standard or transferable skills for modern engineers.

In order to understand what the most important skills to innovate are, we asked the participating engineering students to evaluate eighteen skills on a five-point scale (from "not important" to "vital"). Results indicate, as shown in *Fig. 1*, that soft skills such as open mindedness, objective outlook, creativity, critical thinking and problem-solving capacity are viewed by engineering students as the most valuable skills to innovate. Our findings are consistent with previous results of Passow [4], as knowledge and technical expertise that are generally viewed as basic skills of engineering profession were not considered as being the most important skills.

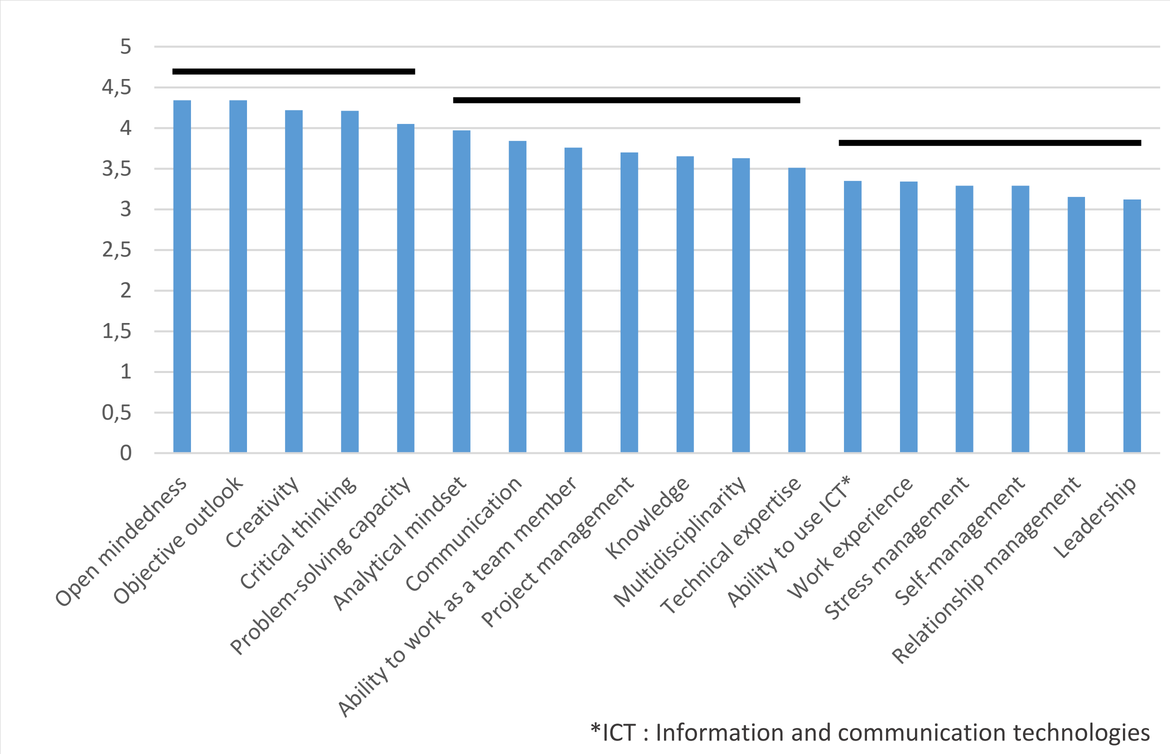

Fig. 1. Engineering students' perception of their skills to innovate

We investigated on how well engineering students perceive they are being prepared in their engineering school to innovate: do they consider they are being sufficiently well-trained or not? Surprisingly, 49.7% of the participants affirmed that they do not feel sufficiently well-trained to innovate. These participants were asked to evaluate the engineering training they are undergoing in their engineering school for each skill on a scale from 'good' to 'poor'. The results of this evaluation are shown in *Fig. 2*, where 1 corresponds to 'poor training' level and 5 corresponds to 'good training' level.

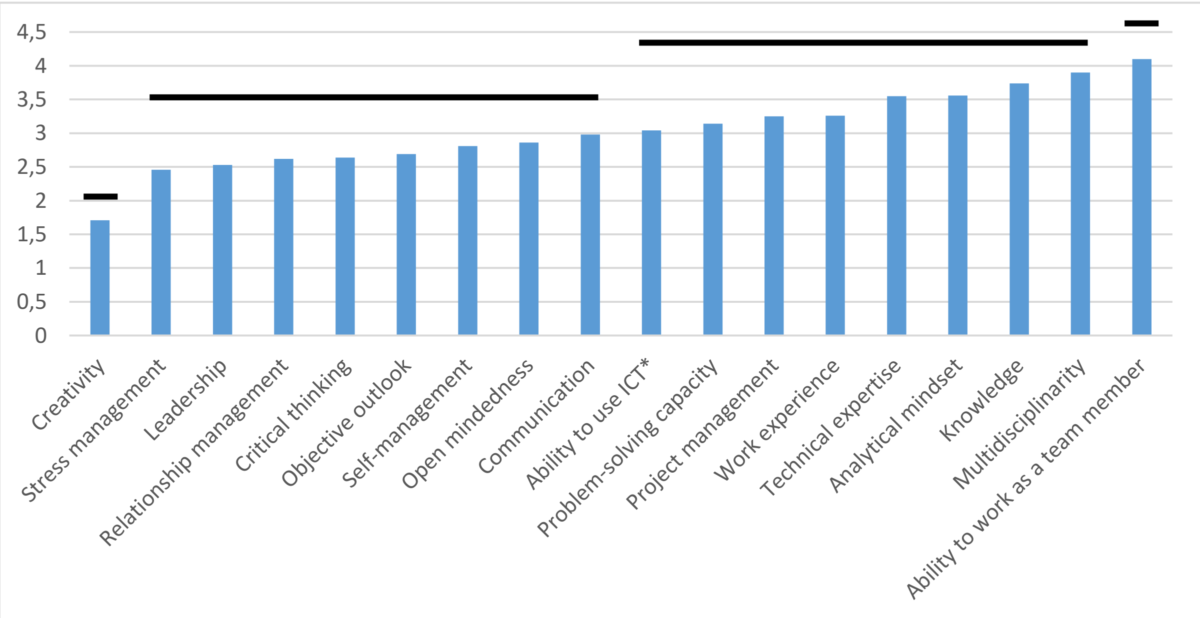

Fig. 2. Engineering students' perception of their training level to innovate

Our results indicate that nearly all the skills considered by the students as being the most important for innovation activities (creativity, critical thinking, objective outlook and open mindedness) are also the ones they feel are the most poorly studied in their curriculum. It is interesting to note that the majority of participants (66.7%) consider that they are not sufficiently trained to develop their creativity. In the conceptual model of Harrison [10], creativity is considered as a cornerstone of innovation activities and one of the most valuable workforce skills for industrial and business organisations. For this reason, the future development of creativity, considered as a valuable intellectual ability, would be beneficial for engineering students and their future employees.

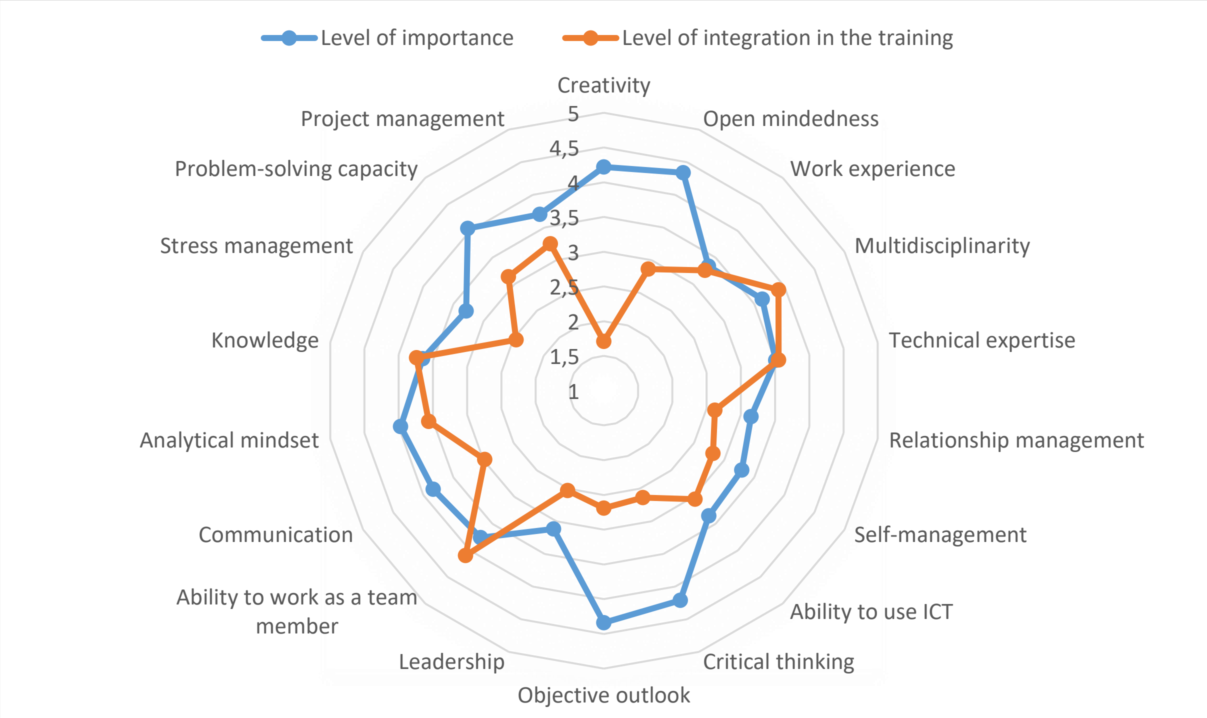

Fig. 3. Comparison between the level of importance and perceive training

We have made a comparison between the two evaluations of skills to innovate in order to observe the deviation between the level of importance and the level of their training perceived by engineering students'. The deviations are shown in *Fig. 3*. On one hand, there is a particularly good match between the perceived level of hard skills like knowledge, technical expertise and experience. On the other hand, we can observe a huge gap between the most important skills for working innovatively like creativity, objective outlook, critical thinking and open mindedness. This outcome is in a sharp contrast with the fact that these skills were considered as the most important skills for innovation activities. However, we can observe a positive deviance only in the case of team working and multidisciplinarity where the perceived training level is slightly beyond of the perceived importance.

4 CONCLUSION AND DISCUSSION

To conclude, our study confirms the importance of integrating innovation skills in the engineering curriculum in order to train modern professional engineers. According to our results, engineering students have a satisfactory evaluation of their training of hard skills needed to innovate. It is not surprising given that these hard skills traditionally benefit from a higher consideration and a stronger emphasis in the curriculum development. Controversially it was not the case for soft skills training. It was evaluated by the majority of students as having an insufficient level. However, these soft skills are considered as more important than hard skills by engineering students, contrary to the traditional perception. We would like to highlight the existing discrepancy between the hard and soft skills development to innovate.

Our research suggests that soft skills to innovate should be better integrated in engineering curriculum to ensure a higher level of innovation capacity for graduate engineers. We are conscious that this integration is a huge challenge and would be difficult to accomplish suddenly, but the results of this study might be taken as a suggestion for a progressive change. For the future generation of modern engineers 'the mastery of innovation skills will become paramount for a successful career [12:60]. Consequently, young engineers' capacity to innovate would be one of the most important elements of their professional skills, having a direct influence on their future employability.

To further our research, we intend to compare engineering students' self-perception of their skills to innovate and the industrial business organisation perception of young graduate engineers' who are freshly employed in their organisations. This study aims to give us a better understanding and clearer vision of how to develop engineering curriculums to reduce the gap between the reality and requirements.

Categorizing student's learning strategy as a basis to improve their educational results.

ABSTRACT

Companies desire for well-educated engineers because they want to optimize the company's processes and invest in technical developments. It is therefore seen as an assignment for Universities to achieve a high efficiency in educating many engineers for these companies. This means that Universities need to attract students and to make sure that the number of dropouts in the first year is minimal. In practice we see the opposite happening. Already in the first semester, students' motivation seems to decrease dramatically and even quite an amount of students leaf the University. This amount needs to be decreased as much as possible. Motivation is related to the learning strategies students use in practice. A tool is developed which enables study Counsellors to measure, to a certain extent, what the learning strategy is of a student and how, if it would be disadvantageous, an unfortunate situation can be changed. Using the tool in practice shows that it would help to lower the dropout rate. The first results seem to be positive. In the coming academic year this tool will be used to a full extent.

Conference Key Areas: Engineering Skills, Curriculum Development, and Attractiveness of Engineering Education.

Keywords: Motivation, first year students, learning strategies, improving methodology

INTRODUCTION

Now, leaving behind the financial crisis, markets again are flourishing. Companies regain markets and are increasingly selling their goods. These companies are investing in innovation of their products, and engineers taking a significant part in the researches to find and realize innovative products, which necessarily need to be sold on those markets. It's seen that on one hand companies desperately are seeking more young engineers to start their career in their companies but on the other hand Universities of engineering need to provide these companies with well-educated starting engineers. Therefore, it is important that Universities of engineering attract many starting students. But often it is the perception of these youngsters that the engineering education is too difficult, using 'complex' mathematics and physics. That could be the cause of many youngsters not to choose for an engineering education. Students, who are starting at the University, encounter most likely a different approach of learning compared to the learning approaches they were accustomed with in their former high schools. In Universities, students themselves need to be responsible for their learning behaviour. It also often occurs that the real educational situations in University do not meet their expectations and perceptions. It is additionally seen that students, nowadays, use their mobile phone in class very often and in some cases students even have a form of game addiction, which makes them having less time for school businesses or even see they need to work during school hours for living. On the other hand, there is a tough scheme of learning activities and they have to come up with positive exam results and tasks relatively fast. As a consequence of some or all of these occurring situations, students develop lack of motivation and, in worst case; they drop out of the University. In [1], [2] and [3], clues for this lack of motivation has already been seen. They also pose some clues for a starting development a lack of motivation in the definition of the four stages of learning strategies of Maslow, especially in the first stage. Students probably enter the University with having an ‘unconsciously incompetent’ attitude in their approach mastering the engineering content of the lectures and other educational programmes. It can be observed these students are frequently making wrong choices in operating their learning styles and controlling their educational programme satisfactorily. To help students in their struggle for mastering the engineering curriculum and becoming good professional engineers, it is important that Universities try to understand what effects their motivation and correspondingly to this, what effects their learning strategies, after which University can help students to regain motivation and have a progressive result in their continuing engineering education.

In 2015, a first paper was presented at the SEFI Conference in Orleans about a research carried out by [Name University], Mechanical Engineering, on what causes to block student’s motivation to continue their engineering education. In the research, it became clear that great numbers of students show their lack of motivation already after the first few weeks of their education. However, the research was not based on finding elements of intrinsic or extrinsic taxonomy of student’s motivation. The purpose of that research was to gain insight into students’ learning strategies in a relatively simple way. From this information it is aimed for to find ways and methods to improve motivation, to ensure that students stay in University and to increase the effectiveness of their work. In [4] an overview study of learning strategies, as it was researched in engineering education, can be found.

The [Name University] approach can be found in the SEFI 2015 paper [5]. A questionnaire was used to ask students about the level they want to reach in terms of a grade, next to the question on how much effort they want to put into their education, in order to reach that grade. From that information 6 categories of learning strategies were distinguished. Where [5] is showing a measurement set up of motivation as it was used in 2015, in this paper the next step is presented. At [Name University] Engineering, Study Counsellor check and help students with their study results. These Study Counsellor are very essential in contact with the students. In their discussions with their students, they are provided with information on motivation of these students. These Study Counsellor than can have discussions with the separate groups of students having the same kind of lack of motivation. They can discuss what is the reason for their lack of motivation and what can be done to regain student’s motivation. These counsellors can discuss improvement of students’ learning strategies. The [Name University] University wants to get more insights into using this tool and to understand better what is happening during the first semester to a student’s motivation. The goal is to take action and to ensure student’s motivation does not eventually result into such dramatically dropout rates. In the paper a conclusion of this research will be drawn, and especially what were the experiences of the Study Counsellor?

1 FINDING STUDENT'S LEARNING STRATEGIES

In our research we see possibilities to measure students' motivation and connect this to their learning strategies in a relatively easy way. In this paper it is the focus how the information coming from the questionnaires can be transformed to advices towards students on how to improve their learning strategies. From the information from the questionnaires, it is supposed students' motivation can be perceived. The students answered the questionnaires in November 2016 and in March 2017. Some questions are included, where students can indicate to what level their motivation is. Also two indirect questions on motivation were asked. 1: What is your commitment to reach for a grade, and 2: How long would you do homework in order to get this grade? In the Netherlands, grades are given in a score from 1 to 10. 5.5 is just a positive grade and lower than that is a negative grade. For the grades 4 levels is used.

1 Just sufficient: students don't have intention to reach more than (5,5-6).
2 Normal grade: this is normally what students will reach (6-7).
3 Higher grade: students really want to achieve higher grade (7-8).
4 Excellent grade: students want to be excellent (8-9).

For the amount of work on doing homework, six stages are defined. The stages are divided from hardly any commitment to do homework (a few minutes of doing homework per day), till having a challenging commitment (more than one and halve hours of doing homework per day). In the next enumeration the six stages of doing homework is listed up.

1 $0 < h < 0.2$ hours/day: No work commitment (<1 hours/week)
2 $0.2 < h < 0.4$ h/d: too little work commitment (1-2 h/w)
3 $0.4 < h < 0.8$ h/d: work commitment for possible positive results (2-4 h/w)
4 $0.8 < h < 1.2$ h/d: more than normal commitment (4-6 h/w)
5 $1.2 < h < 1.6$ h/d: hard working commitment (6-8 h/w)
6 $h > 1.6$ h/d: Extensive work commitment (>8 h/w)

With these two data combined in a two-dimensional graph, an estimation of categories on learning strategies of the students can be acquired. In the two-dimensional graph below, Figure 1, zones of certain learning strategies are shown. When students showing their commitment to what level of grade they want to reach in combination to the amount of hours of homework they want to spend to get this grade is seen as combined information to which a classification of learning strategies can be identified. This learning strategy of the student is the basis where personal study coaches can have discussion on in order to help this student making decisions accepting a more effective learning strategy and gather a better result for the upcoming education.

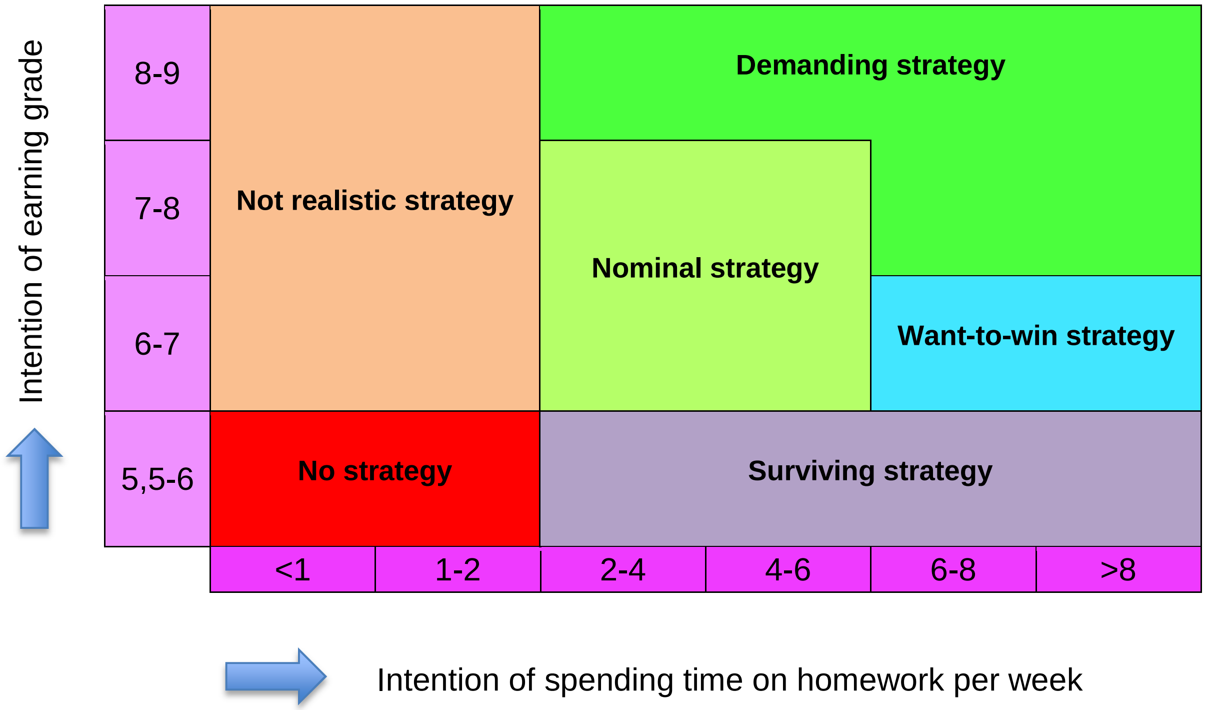

Fig. 1. Attempt to classify levels of learning strategies

In Figure 1 six different students' learning strategies were distinct:

1. **Demanding strategy:** students want to work very hard in order to achieve the highest grades possible. Often these students can easily have good results in their education and want to do special work, e.g. doing an honours programme.
2. **Want-to-win strategy:** students estimate that spending the maximum amount of time on homework will enable them to have average/sufficient marks. These students see they need to work hard to get higher grades and they are very motivated to do extra work to get normal grades.
3. **Survival strategy:** students think they need to work hard for getting an engineering degree. They believe or feel they have not the right cognitive capabilities to get normal grades, so they are willing to work very hard to achieve this goal.
4. **Nominal strategy:** students' intent to achieve good marks by working a nominal amount of time on homework. These students are seen as students achieving nominal educational results by working a nominal time on their homework.
5. **Not realistic strategy:** students' work under the assumption that they are able to invest a minimum amount of time to no time for their homework and nonetheless getting maximum high marks. But it can also be that these students are brilliant and need to go to the academic University or they have arrogant thinking that the education is too easy for them.
6. **No strategy:** students without specific strategy. It can be the case that these students are struggling for finding out if mechanical engineering is really something for them.

Helping students to change their learning strategies is concerning students selected for the learning strategies: 'Not realistic strategy', 'No strategy' and 'Surviving' Strategy. The approach is to convince students to change their way of learning to the other learning strategies. In Figure 2 the arrows are showing what the intention is of the Study Counsellor. They want to discuss with students on how to change their unfortunate learning strategy into a more successful strategy.

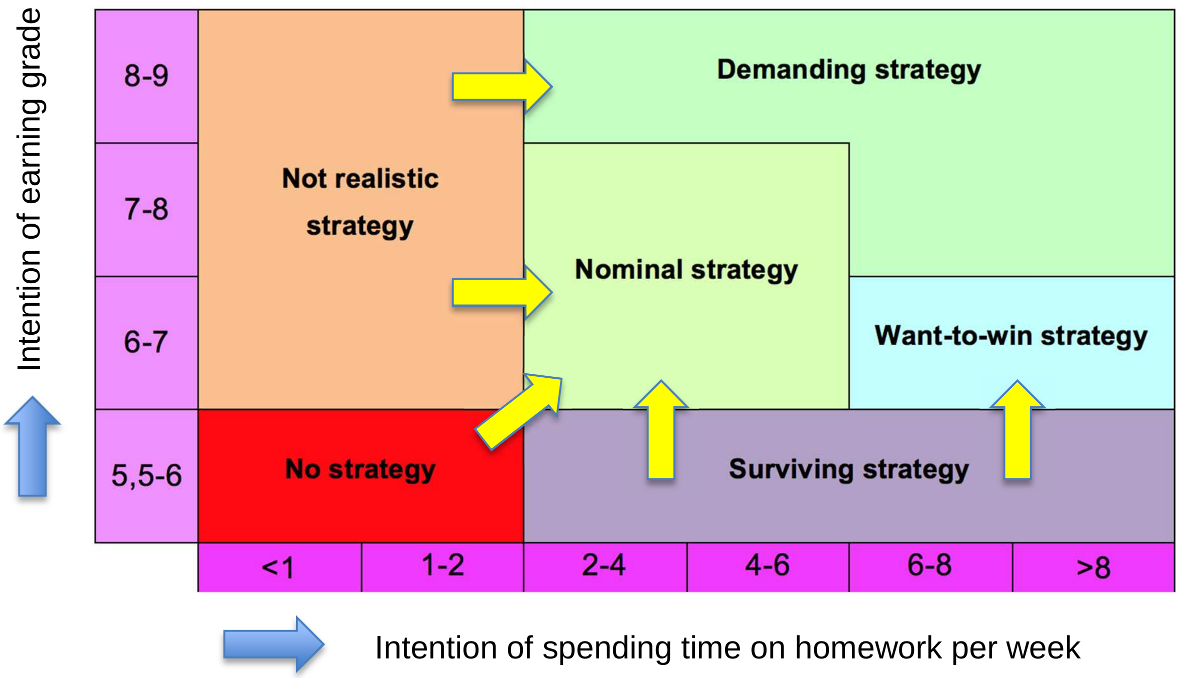

Fig. 2. Change direction of non-effective learning strategies to the more effective

In the methodology composed Study Counsellor are an important element really being able to discuss with students changing their unfortunate learning strategies into more fruitful learning strategies. But how this discussing should take place? Especially for this intervention a questioning and answering table was assembled. In Table 1 in total 13 questions were formulated. Students can answer in a 5-point Likert scale. But it is always the question what are the perceptions of the students answering to the questions. What is their perception to fill in a 3 and is this the same perception for another student? It is likely each student has his own perception about the five levels of answering. In order to harmonize the answering each level of the Likert scale is given a written answer. Students have to choose which of those five answers are the most likely to their situation.

Students can choose the right answer to their situation. Study Counsellor can use, for each student, the outcome of filling in this table as discussion items. To the far right (5) students, to their opinion really function perfectly, while to the far left students really expressing themselves that there is something not okay. Counsellors can use the outcome as a discussion document on which they can consider together with the student what is the best thing to do, and how a student can change from the left side more to the direction of the right side? So the table can be used to give students possibilities to express their motivation and an advice to change their motivation in order to obtain better results in the engineering education. In the next paragraph the outcome of the inquiry will be presented.

Table 1. Answering table formulating student's learning strategy

	QUESTION	ANSWER				
		1	2	3	4	5
1	**What do you expect from your education?**	I don't see education is helping me realize my career wishes.	I'm struggling if this is what I want, but I want do technical education.	I have difficulties to focus what to become in my career.	I know that engineering is what I want. But I need specialisation focus.	I really can grow. I see what to become. I want to do more.
1[a]	**How does your environment effect your education?**	Somehow it was not my decision to come to engineering.	I'm doubtful about right education. My environment isn't supportive.	It was my decision, but I cannot discuss this with my environment.	I see in my environment what is the work of an engineer. I like that.	My parents really are proud about me and my friends too.
2	**Do you accept your educational situation?**	I can't accept the today's situation. I want to change it.	I want information about going somewhere else.	I doubting if this situation is what I want.	I accept today's situation, but I want to make some changes.	I fully accept my today's situation.
2[a]	**Do you accept the demand of doing homework?**	Homework is not what I want. I make no homework.	I can't get the motivation to do homework.	I'm doing just what I think is needed to pass exams.	I see that if I don't make homework I won't pass exams	I'm focussing on higher grades, so I do homework to be able to get those.
2[aa]	**Are you aware of the success factors getting positive grads?**	I don't know and don't want to know what success criteria are.	I don't know why success criteria will help me.	I want to know what success criteria are.	For some courses I do know but for other I don't know.	I know for every course what the success criteria are.
2[ab]	**Are you resilient when things are going wrong?**	I see my results are bad but I don't want to do more work.	I thought I couldn't engineering and it seems I was right.	I'm not demotivated, but when things are going wrong it demotivates me.	I see it is important to do work extra hard, but I have several other things to do.	I can find extra motivation to do things better after they went wrong.
2[b]	**Do you see the demands of doing engineering work?**	I don't know what the demands of engineering are. It's about Physics.	I will see what the demands are. Now I'm focussing on my education results.	I'm eager what the demands of engineering are.	I know, in some cases, what the demands of engineering are.	I see what an engineer needs to do. I work already in an engineering company.
2[ba]	**Are appealed to the Engineering work?**	I think I'm not on the right education.	I doubt if engineering is my education.	I know that the engineering profession is giving me a good career.	Engineering is really what I want, but not in which kind of engineering direction.	Engineering is really what I want. I know what I want to become in this profession.
2[bb]	**Do you have perceptions of your future profession?**	I don't know if engineering is part of my feel good in the future.	I want to talk to someone who can tell me more about an engineer career.	I need to have more information what a possible engineering task contains.	Engineering is really my career but I don't know in what kind of company.	I already know what I want to reach in the future in an engineering job.
3	**What were your grades in preparatory school?**	I just passed. For mathematics I had a negative grade	I just passed. For mathematics was just positive.	I passed quite easily. For mathematics I had a high grade.	I had all grades positive, but not very high	I had high grades for every part.
3[a]	**What is your intellectual capability?**	I feel I can't understand the engineering knowledge. Especially mathematics.	I think I can get my propaedeutic certificate in two years if I work hard.	I must work hard to get my propaedeutic certificate in 1 year.	My results are good. I'm going to pass in 1 year.	I'm really doing well. My mean grade is > 7.
4	**What is your financial situation?**	I have to do everything alone. I must work for living.	Sometimes I think what to do about my financial situation.	My financial situation is not hindering me doing the engineering education.	My financial situation is not a problem.	I have no financial problems. My parents helping me.
5	**Do you have the will to change your learning strategies when needed?**	No, it is taking me too much time.	I want to change only if it is not effecting my daily live.	I don't know. Can I get some help of someone?	If it makes me getting better, I'm certainly willing to change.	My strategy is ok and my results too.

2 DATA

The method proposed in the previous section is used to map the learning strategies and study motivation of Mechanical Engineering students that started their education in the academic year 2016-2017. We asked the students to fill out the questionnaire twice and see whether their learning strategies and study motivation change in time during the year. The first time we questioned them was in November 2016 and the second time in March 2017.

2.1 Results of the questionnaire

The distribution of the students per learning strategy is found in *Table 2*. Between 2016, November and 2017, March already 20 students decided to quit the education (16%). There were only 17 students that participated in both the survey in November 2016 and the one in March 2017. From this subgroup of students, 12 students didn't change the learning strategy during that period. Three of them moved from want-to-win strategy to surviving strategy, one student from demanding strategy to want-to-win strategy and one student from nominal strategy to not-realistic strategy.

Table 2 Information and results of the motivation questionnaire

	2016, November	**2017, March**
# students	122	102
# respondents	37	66
# no strategy	0	2
# not realistic strategy	0	0
# surviving strategy	7	11
# nominal strategy	9	18
# want-to-win strategy	13	26
# demanding strategy	8	9

After the first semester Study Counsellors give each student a Study Progress Indication (SPI). This indication is practically based on the number of credit point obtained at the moment the SPI is awarded by the study coach. The Study Progress Indication is to be explained as:

A – On schedule (student progress is up to standard)
B – Initial signs of study delay
C – Considerable study delay
D – Serious study delay

An SPI – D at the end of the first year means that the student has obtained less than 45 credit points out of 60 and therefore, as it is the policy out education, has to quit the educational program. We will use this indicator to validate the information from the Tables 2 and 3.

Table 3 SPI at the moment the third questionnaire is filled out.

	STUDY PROGRESS INDICATION			
	A	**B**	**C**	**D**
# no strategy	0	1	1	0
# not realistic strategy	0	0	0	0
# surviving strategy	1	1	5	4
# nominal strategy	0	6	8	4
# want-to-win strategy	2	8	9	7
# demanding strategy	2	4	2	1

Students with a D indication in March are considerable candidates to leave the education at the end of the year. The majority of these students have a want-to-win strategy, surviving strategy or nominal strategy. This indicates that these students say we want to do our best to achieve positive grades but the reality is otherwise. Study Counsellors can discuss with these students what the reason was for these severe delays in learning results. For these students it is the last call to change. Otherwise they are really not capable to stand the demands of the education.

Another good indicator for the possibility in succeeding the engineering education is the final grade for mathematics in the secondary school, since we see this as a relevant indicator that shows, to some extent, the learning capacity of a student, entering the University education. The students entering our University are coming from the VWO (Secondary school level for academic education), as well from HAVO (Secondary school level for bachelor education) and from a middle technical occupational school. From this last group we don't have information on their final grades on mathematics. In Table 4 those grades are given for the respondents to the survey in March 2017. None of the students got an 8 as a final grade for mathematics in their secondary school.

Table 4 Final grades for mathematics in secondary school per learning strategy.

	FINAL GRADE MATHEMATICS			
	5	**6**	**7**	**9**
# no strategy	0	0	2	0
# not realistic strategy	0	0	0	0
# surviving strategy	3	3	5	0
# nominal strategy	1	5	11	1
# want-to-win strategy	1	13	12	0
# demanding strategy	0	3	6	0

Except for the categorisation in learning strategy, the students also respond on the questionnaire of 13 questions from Table 1. The answers from the respondents in March are graphically represented in Fig. 3.

From Fig. 3 Is becomes clear that only incidentally students answer with option one. Option two is more often present as an answer, especially for questions 2, 3[a] and 4.

Fig. 3 The distribution of answers options given by the students per question.

The results seen in the Figure 3 show that coaches really can have topics to discuss with students in order to understand the background of their not so successful study results. Especially level of answers 1 and 2 give reasons for Counsellors to have discussion with students. As an example, on question 4 students really see the financial situation as an obstacle to spent their attention to education. Counsellors can than discuss the reason and try to discuss, as an example, to lend more money from government, as in the Netherlands students are given the possibility to loan money from Government under relatively advantageous terms. (Low rate and advantageous pay back condition.)

2.2 Results of a single class

As a test case we take a closer look at a single class of 11 Dutch students Mechanical Engineering. The students have filled out the questionnaire. The classification in learning strategies is graphically represented in Fig. 4. Their answers to the questions are given in Table 5.

The first observation is that incidentally all of these students respond with answer 4 to question 5: each one of them is willing to change the learning strategy if it makes him/her getting better. This definitely could be seen as a positive sign to discuss with these students what the best way is to change their learning strategy.

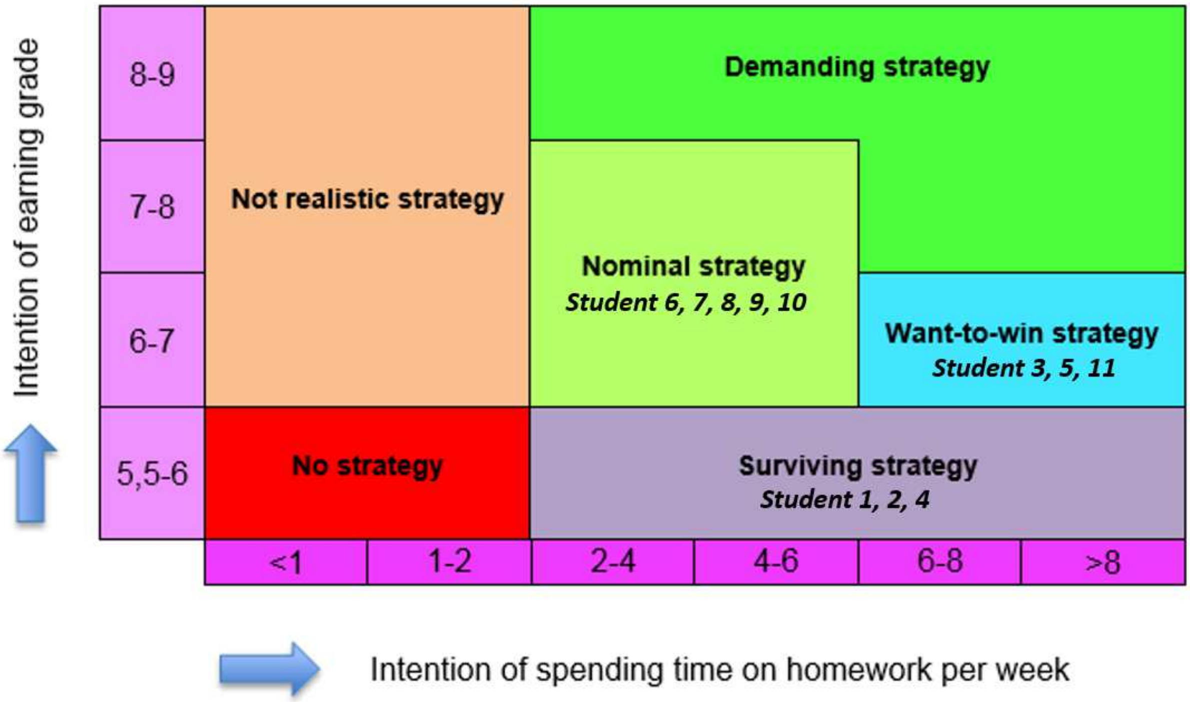

Fig. 4 Classification of students from the test group in the six possible learning strategy categories, according to Fig 1.

Table 5 Answers to the questions (see Table 1) from the students in the test group.

STUDENT	**QUESTION**												
	1	**1^a**	**2**	**2^a**	**2^{aa}**	**2^{ab}**	**2^b**	**2^{ba}**	**2^{bb}**	**3**	**3^a**	**4**	**5**
Student 1	4	5	4	3	4	4	4	4	3	3	3	4	4
Student 2	2	4	3	4	4	2	4	5	2	4	2	3	4
Student 3	4	4	5	4	5	4	3	4	3	4	4	4	4
Student 4	4	5	1	4	4	3	4	5	4	5	2	1	4
Student 5	4	4	4	2	4	3	4	4	4	4	2	2	4
Student 6	4	4	4	4	4	4	4	4	4	2	2	3	4
Student 7	3	4	4	5	5	5	3	4	4	4	3	4	4
Student 8	5	5	4	4	4	4	4	5	4	5	2	3	4
Student 9	4	2	4	4	3	4	5	2	2	4	2	5	4
Student 10	4	5	4	3	4	4	5	4	4	2	3	4	4
Student 11	4	5	3	4	5	5	2	4	2	4	2	4	4

2.3 Feedback from the Study Counsellors and students

Based on the student's study progress and his/her answers to the questionnaire, study development coaches reflect on the results with the individual student in a one-to-one conversation in order to find a way to improve the learning strategy. Study Counsellors put the method into practise. Summarizing the experiences of both the students and the study coaches:

1. The questionnaire provides good input for a conversation and gives clues and directions on how to improve students study results. Best would be to use the method in the first week of the academic year. Halfway the academic year students find it hard to change their direction.
2. Students mention that the survey increases their level of awareness with respect to study motivation. Two aspects have influence on the motivation:
   a. Although students like the education in Mechanical Engineering, they don’t know exactly what it will lead to for their future professional careers. More orientation on career possibilities during the first year would be most welcome. Seeing the purpose of their education would increase the motivation.
   b. Most courses examine in two or more separate parts. Credit points (ECTS, European Credit Transfer System) will only be awarded when a student passes all separate exams. When a student misses one part or more, then no ECTS will be awarded, although in fact the student might have gained “virtual” credit points for the parts he/she did pass. This also influences the motivation.
3. The classification of students in the six categories of learning strategies, as specified in section 1, agrees with the perception of both the Study Counsellors and the students on how the student performs at the moment. Student said: “I agree to be put in the certain learning strategy”.
4. The method also works for discussing and raising awareness with a group of students placed in a same learning strategy at the same time. They inspire each other by explaining how to study.

3 SUMMARY AND ACKNOWLEDGMENTS

This paper is giving information about the procedure at [Name University] University of applied Sciences in [place] on how they approach the effect of the occurring situation of lack of motivation of students during the first year. The information gathered can be seen as positive to the use of the new method on the improvement of learning strategies. The result encourages the staff to continue using this method right from the start when students enter the University. The relatively positive feedback from students as well as from accompanying teacher coaches gives us the power to continue with this learning strategy tool. From the next educational year this tool will be used to all students right from the start when they are entering our education. We feel that this method gives us the opportunity to really improve student’s learning strategy and therefore increase students’ educational results and therefore also their motivation.

ABSTRACT

The European Project Semester (EPS) is a one semester capstone project/internship framework offered by the EPS providers to engineering, product design and business undergraduates. While a student-centred project-based learning offer, EPS proposes a unique multidisciplinary and multicultural teamwork set up to promote soft, technical and scientific competencies. In the spring of 2016, the EPS at the Instituto Superior de Engenharia do Porto (ISEP) welcomed a team of engineering students who chose to develop a sustainable water desalinator, the working principle relying on solar energy and natural temperature differences to convert saline water into fresh water. This paper describes the team's journey, including the motivation, the solution design process, considering the technical & scientific state of the art as well as the potential impact in terms of ethics, sustainability and marketing, and the development and testing of the prototype. The results obtained validate the purpose of the developed system since a significant reduction of the salt water conductivity, to values of the same order of magnitude of tap water, were observed. Although improvements can be made, the desalinator prototype produced 70 ml/d of distilled water in late spring and 7 ml/d in midwinter atmospheric conditions.

countries – the EPS providers. The EPS defines a common structure composed of a multidisciplinary project module together with a set of project supportive modules devoted to soft skills, aiming to prepare students for international collaboration. The EPS providers implement the programme in accordance to a set of core rules, the "10 Golden Rules of EPS[2]". These rules specify, among other features, that English is the working language, teams must be formed by students from different countries, and it is worth 30 ECTS credit units (ECTU). Despite this common structure, each institution enjoys some freedom in the implementation of EPS. The programme is addressed mainly to incoming exchange students so that the class becomes a truly international setting. The goal of the EPS is to expose participants to diversity, both cultural and scientific, teamwork and multidisciplinary problem-solving [1].

ISEP offers EPS to 3rd and 4th year engineering, business and product design students every spring semester since 2011. The EPS@ISEP assigns 20 ECTU to the project module and 10 ECTU to complementary project supportive modules: Project Management and Team Work; Marketing and Communication; Foreign Language; Energy and Sustainable Development; and Ethics and Deontology. EPS@ISEP has been challenging students from multiple educational backgrounds and nationalities to join their competences to solve multidisciplinary real life problems in close collaboration with industrial partners and research institutes. This approach stimulates students to contribute with and apply their specific knowledge and develop transversal skills, namely social and communicative skills, during the different stages of the team collaboration process [2].

In the spring of 2016, a team of civil, packaging, mechanical, electrical and logistics engineering students chose to develop a sustainable water desalination module. The team embraced this challenge motivated by the idea of providing a sustainable source of drinkable water to populations located in coastal areas where water is scarce and/or contaminated. The team, driven by this opportunity, decided to design, build and test a sustainable desalination system using solar energy. Solar distillation involves direct absorption of solar energy in the saline water and its evaporation (at a temperature substantially below the normal boiling point) in an enclosed space. In contrast to the fossil fuel powered desalination, solar desalination is a sustainable process. This process removes impurities, such as salts and heavy metals, as well as eliminates microbiological organisms. The purified water can be used for human and animal consumption, farming, gardening, etc. The team decided that their system was intended for human and defined as their main marketing target governmental institutions, non-governmental organisations (NGO) and environmentally aware individuals. The team first conducted a state of the art review together with sustainability, ethical and marketing studies in order to define the use cases and requirements of their system. Based on these requirements, the team designed the structure and control system, chose and procured the materials and components and, finally, built, tested and determined the average daily volume of distilled water obtained with their solar powered desalination prototype.

This paper is organised in six sections. Section 1 presents existing desalination methodologies and describes the team own approach. Section 2 presents the complementary analysis performed by the team in terms of sustainability, marketing and ethics. Section 3 describes the proposed solution, whereas Section 4 reports the functional tests as well as its results and Section 5 draws the main conclusions.

1 WATER DESALINATION

The most common chemical-free water desalination processes are Vapour Compression, Reverse Osmosis, Direct Contact Membrane Distillation and Water Desalination Powered by Renewable Energy Sources [3].

Vapour Compression process evaporates the salt water by using heat delivered by compressed vapour, as shown in *Fig. 1*. This type of desalination requires a mechanical driven compressor or a blower connected to the mains. The team rejected this technique for its expensiveness and high consumption of energy.

Reverse osmosis, relies on high pressure to overcome the osmotic pressure of a membrane, forcing the water through the membrane while retaining salt and other minerals (*Fig. 2*) [4]. Although an efficient technology, the team rejected it for being complex, difficult to downscale, expensive and susceptible to membrane fouling [5].

The direct contact membrane distillation process relies on a membrane dividing a container in two parts, at distinct temperatures (*Fig. 3*). The vapour flows from the heated tank, through the membrane, into the lower temperature tank, where the vapour condenses into drinkable water [6]. Although compatible with downscaling, this approach suffers from high energy consumption [5] and a cost incompatible with the available budget.

Sustainable water desalination systems are powered by renewable energy sources. As an example, solar power desalination relies on the Sun to convert saline water into fresh water [7]. The Sun heats the salt water, which evaporates and, then, condensates on the transparent cover. Finally, drinkable water can be collected (*Fig. 4*).

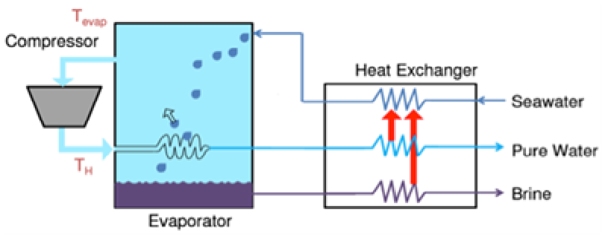

Fig. 1. Vapour Compression [4]

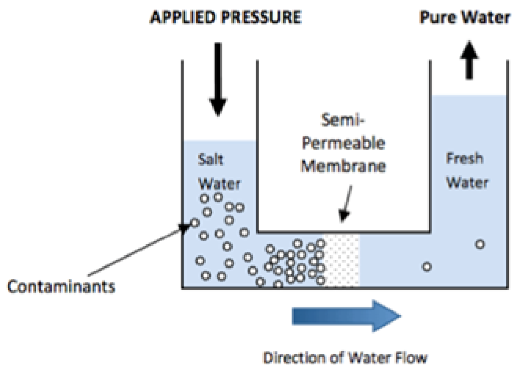

Fig. 2. Reverse Osmosis [8]

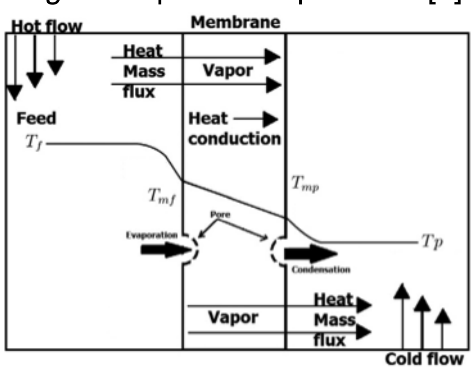

Fig. 3. Direct Contact Membrane Distillation [6]

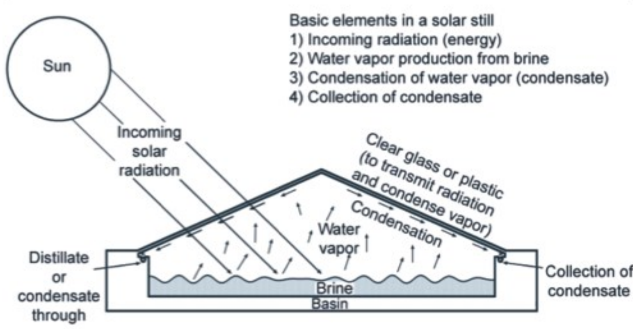

Fig. 4. Solar powered water desalination [7]

The team, under the motto “You don't need to be a fish to drink seawater”, chose to develop a modular solar powered desalination system named “Water Pyramid”.

Furthermore, the Water Pyramid should be modular, scalable and low cost.

2 COMPLEMENTARY STUDIES

The goal of this project was not just to build a working prototype, but to adopt a comprehensive approach considering the distinct relevant perspectives when developing a product like the Water Pyramid, namely, Marketing, Sustainability and Ethics. The idea is to make the team consider the development of a product, rather than just a technical proof of concept prototype, including the eventual creation of a company.

2.1 Marketing

The team defined as their target governmental institutions, NGO and environmentally aware individuals. Governments and NGO could provide the desalination module at reduced or no cost to dislocated or low-income people living close to the coast. Eco-friendly individuals, *e.g.*, nature lovers or outdoor sports practitioners, could also buy and use the product while exploring remote coastal areas. In addition, the module could also be marketed as an educational tool to: (*i*) promote environmental education by raising the awareness for the need to preserve, save and share existing water resources; and (*ii*) enrich the learning experience in the field of thermodynamics, *e.g.*, by performing experiences involving unpredictable factors such as the meteorological conditions, as well as in the field of data acquisition and automation, by providing a stimulating set up covering different areas such as sensor selection, Internet of Things and cloud based computing (sharing the data available).

2.2 Sustainability

Sustainability is a holistic concept involving economic, social and environmental perspectives. In this project, the resulting product – an affordable solar powered desalination module for households – is expected to have a good market acceptance and pay itself, considering there will be no further need to buy bottled water.

The team envisioned the creation of a company to develop and market an eco-friendly domestic water desalination product. The company is not just focussed on selling and making profits, but above all in meeting the users' needs and expectations. Based on these ideas, the team decided to use raw materials and sustainable energy sources (sunlight rather than fossil fuels) to minimise the generation of environmental pollution. On the one hand, a domestic scale system places the burden of the operation know how on the customer side. On the other hand, it can also mean a strong personal customer service where a company instructor will demonstrate how to operate and explain the relevance of the desalinator from a sustainable development perspective.

2.3 Ethics

In terms of code of ethics, the team chose the American Academy of Water Resources Engineers (AAWRE) code for the Water Pyramid. This code specifies a set of good practices standards regarding water resources for engineers [9], *i.e.*, helps engineers to adopt a professional practice and individual behaviour conducive to the preservation and respect towards existing water resources. The objectives of the AAWRE are the: (*i*) identification and certification of engineers with specialized knowledge in water resources for the benefit of the public; (*ii*) recognition of the ethical practice of water resources engineering at the expert level; (*iii*) enhancement of the practice of water resources engineering; (*iv*) support and promotion of positions on water resources issues important to the public health, safety and welfare; and (*v*) encouragement of life-long learning and continued professional development. In particular, the team decided to focus on objectives *ii* and *iii*.

3 WATER PYRAMID

Standard strategies to provide fresh water to human populations imply typically high energy costs. The challenge of this project was to design, build and test a sustainable water desalinator module for a multifunctional dome with minimum energy consumption. The Water Pyramid was designed to be placed on top of a modular wooden dome described in [10], *i.e.*, to become the top module of the dome.

3.1 Structure

The Water Pyramid (*Fig. 5*) includes fresh and salt water containers for desalination, a transparent cover to allow the passage of the sunlight in and to condensate the evaporated water as well as external fresh, salt water and leftovers storage tanks. Three pipes connect the pyramid with the different storage tanks. The fresh water container is the white pentagonal base, with a 3º slope to ensure the drinkable water flows into the fresh water storage tank. The black salt water container, with a 1000 ml capacity, is centred in respect to the white base and placed horizontally to optimize evaporation. The transparent cover is made of five triangles with an inclination of approximately 30º. The resulting pyramidal cover is easier and more economical to build than the intended bowl shape. *Fig. 6* shows a general view of the structure and a cross section. For the cover, the team chose transparent polymethylmethacrylate (PMMA) instead of glass because: (*i*) typical PMMA grades allow the passage of 92 % of the sunlight, including ultraviolet (UV), which speeds up the process; (*ii*) the thickness does not affect the transparency; (*iii*) the lightness and hardness of the material; and (*iv*) the manufacturing process does not involve toxic materials or heavy metals. The salt container is made of black plastic – a flowerpot coaster – to absorb heat and increase the distillation process efficiency.

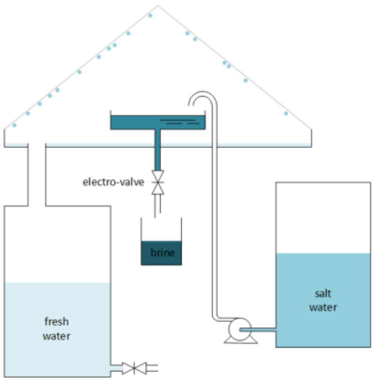

Fig. 5. Water Pyramid system

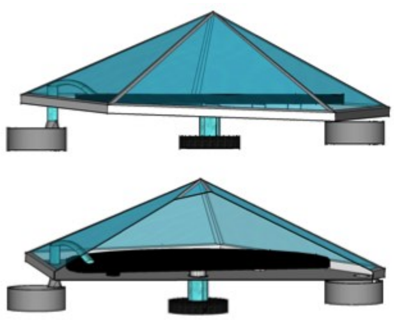

Fig. 6. General view of the structure and cross section

3.2 Working Principle

The desalination starts with the pumping of salt water from the external storage tank into the black container. As the sunlight passes through the transparent cover, it heats the inside of the pyramid, raising the inside temperature – greenhouse effect – and, consequently, decreasing the relative humidity and increasing the ability to evaporate the salt water. Due to the temperature difference between the inner and outer sides of the PMMA cover, the water vapour condensates on the inner side and runs down into the white base container. Finally, the drinkable water flows through the sloping surface of the white container into the external fresh water tank.

The black container needs to be periodically emptied of the process leftovers. In order to remove the highly concentrated brine remaining in the black container, the system opens the electro-valve, which connects the black container with the leftovers tank, and turns on the salt water pump to help draining the brine from the black container into the leftovers tank, and, finally, closes the electro-valve.

3.3 Control System

The team designed an electronic control system to make the Water Pyramid autonomous. The system comprises a micro-controller, a pump (output), an electro-valve (output) and four ultrasonic sensors (inputs). To prevent overflows, two ultrasonic sensors measure the maximum level of the water in the internal salt water container and in the external fresh water storage tank. The remaining two ultrasonic sensors measure the minimum level of water in the internal salt water container and in the external fresh water storage tank. These sensors are responsible for the removal of the leftovers from the black container and for the restart of the process when the fresh water tank is below its capacity. To prevent salt deposition in the black container, the system refills the black salt water container whenever the low level sensor detects a level corresponding to approximately 100 ml of salt water by opening the electro-valve (*Fig. 5*). The micro-controller, based on the measurements of the level sensors, operates the pump – to fill the black container with salt water – and the electro-valve – to remove the leftovers from the black container.

4 EXPERIMENTS AND RESULTS

To evaluate the performance of the prototype, two experiments were carried out. The first was focussed on proving the concept and detecting problems in the prototype (late spring) and the second on establishing the performance of the system in a worst case situation (midwinter). While the late spring experiment lasted one day, the midwinter one took 27 days. All experiments were performed using a 1 to 5 scaled prototype of the real structure to reduce costs and improve transportability, while achieving the same functionality.

The initial experiment took place on June 2016 (late spring) in an obstacle free area (the terrace of building F). Specifically, the prototype was placed at N 41º10'45.26'', W 08º36'29.21'' and data was collected from 8th June 2016 till 9th June 2016. In this 24-hour period, the prototype collected 70 ml of fresh water. In terms of average temperature values, the brine and the inside of the pyramid were 15 % and 13 % warmer than the outside, respectively. Concerning the average relative humidity, the value inside of the pyramid was 35 % higher than outside. *Fig. 7* illustrates the evaporated water conduction under the cover. The condensed fresh water flows down the cover inner walls into the white container as shown in *Fig. 8*.

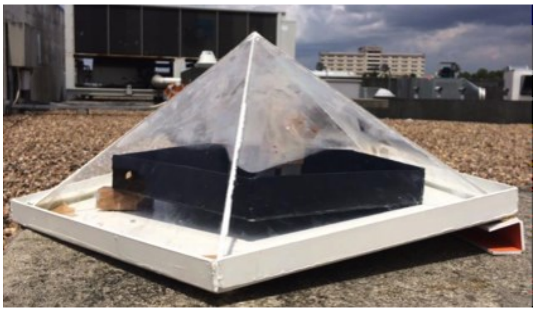

Fig. 7. Conduction on the cover

Fig. 8. Condensation process

The second experiment was conducted during the winter from 8th December 2016 to 4th January 2017. The prototype was positioned on an obstacle free horizontal surface located at N 41º13'39.67'', W 8º36'53.96''. *Fig. 9* displays the daily temperature and relative humidity conditions, including the outside air temperature (navy blue), inside air temperature (light blue) and brine temperature (red), outside air relative humidity (orange) and inside air relative humidity (green). Considering the average values, the brine solution was 7 % warmer than the outside air, whereas the average inside air temperature was 6 % higher than the average outside air temperature. In terms of the average relative humidity, the relative humidity inside the device was 14 % higher than outside.

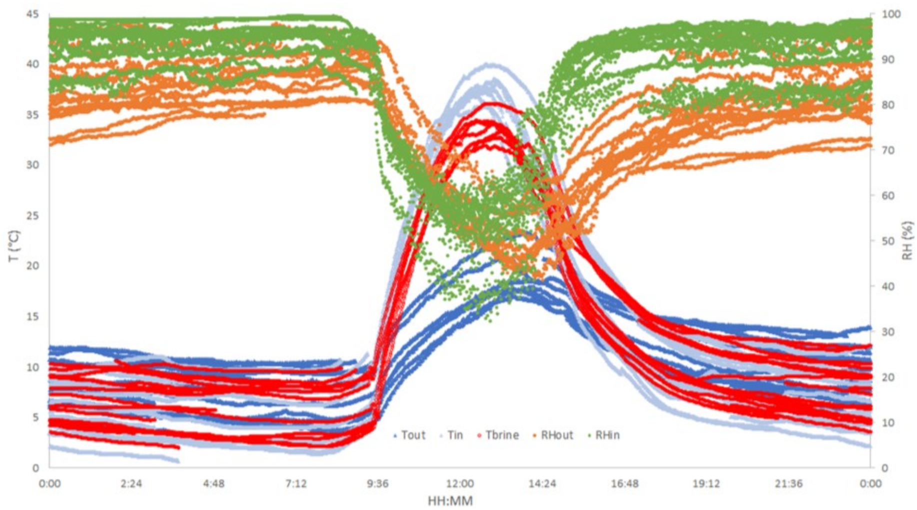

Fig. 9. Daily temperature (outside, inside and brine) and relative humidity (outside and inside) during the midwinter test

Table 1 summarises the results of both experiments concerning the average, minimum and maximum values of the temperature (T) in ºC of the (B)rine, (I)nside and (O)utside the pyramid, the minimum and maximum relative humidity (RH) in % (I)nside and (O)utside the pyramid and the daily volume of distilled water (DW) in ml. As expected, the late spring temperature and relative humidity were, respectively, higher and lower than the corresponding midwinter values. The average daily volume of distilled water in late spring was 70 ml and in midwinter 7 ml.

Table 1 Spring and winter results

		T (ºC)			RH (%)		DW/d (ml)
		B	I	O	I	O	
Spring	Avg	25.5	24.7	22.1	83.7	62.0	70
	Min	17.9	16.6	15.9	31.4	15.0	
	Max	49.9	61.2	43.6	95,7	83.7	
Winter	Avg	11.0	10.9	10.2	88.9	78.3	7
	Min	02.0	00.6	03.3	32.5	41.5	
	Max	36.1	40.0	23.3	99.7	98.5	

The electrical conductivity (EC) of the salt water and of the fresh water obtained after desalination was evaluated using a WTW LF 538 Conductivity Meter. EC decreased from 5.05 S/m to 0.154 S/m, indicating that a significant reduction in the salt water concentration occurred as a consequence of the desalination process.

5 CONCLUSIONS AND ACKNOWLEDGEMENTS

The EPS@ISEP framework provided a holistic, multicultural and multidisciplinary learning environment. First, the team specified and justified the requirements of their design solution – the Solar Pyramid – based on multiple team studies, brainstorming and coaching. These studies involved marketing, sustainability, ethics and deontology, as well as water desalination principles. After, the students selected, procured and acquired the materials and components from local suppliers. Next, they developed and tested a scaled model. The tests allowed the team to: (*i*) identify and correct assembling problems; and (*ii*) verify experimentally that the yield of the process depends on the atmospheric conditions, enabling the team to confirm the Solar Pyramid potential for regions with high atmospheric temperature range even in low relative humidity conditions. In terms of the learning experience, the team considered that the "*European Project Semester enriched all team members with culture, teamwork and team bonding*".

This work was partially financed by the ERDF – European Regional Development Fund through the Operational Programme for Competitiveness and Internationalisation – COMPETE 2020 Programme within project POCI-01-0145-FEDER-006961, and by National Funds through the FCT – Fundação para a Ciência e a Tecnologia (Portuguese Foundation for Science and Technology) as part of project UID/EEA/50014/2013.

ABSTRACT

Although there is high degree of agreement on the importance of transversal skills for engineers, employers observe a significant gap between expectations and reality. This paper discusses the need for the development of a framework of professional roles for future engineers and the implementation of dedicated skills education in engineering curricula to train students for this role. Based on an extensive literature study, an

overview is given of previous research on this topic. The paper also outlines the next steps that will be taken by the authors as part of a European project PREFER to develop and implement these roles in engineering education.

Conference Key Areas: Continuing Engineering Education and Lifelong Learning; Skills and Engineering Education; Curriculum Development

Keywords: Labour market entry; Transversal skills; Professional roles; Skills mismatch

INTRODUCTION

A large survey among 467 Flemish engineers who graduated between 2014-2016, indicated that 22% of the respondents were no longer working with their first employer. Almost half of these graduates left because the job did not meet their expectations [1]. The European project PREFER (Professional Roles and Employability of Future Engineers) aims to reduce the skills mismatch in the field of engineering. Managers of human resources departments report that fresh engineering graduates frequently display (1) a lack of transversal skills required by the labour market and (2) a lack of self-awareness of their own strengths and weaknesses and of who they are as an engineer.

The objectives of the PREFER project are threefold. First, we aim to construct a Professional Roles Framework. This framework will describe the different roles engineers can take on at the beginning of their career, independently of the engineering discipline (e.g. electrical, mechanical, chemical). Each role will be characterized by an associated set of transversal skills. Thereafter, a Test System will be developed in order to (1) increase engineering students' awareness of the multitude of professional roles in engineering and (2) to make them reflect on their own engineering identity and their interests, strengths, and weaknesses. Thirdly, we will explore how to implement these innovative tools in the engineering curriculum by running a number of pilots in the participating universities.

In order to realize the PREFER objectives, a well-balanced consortium was built with both universities (University of Leuven [Belgium], Delft University of Technology [The Netherlands] and Dublin Institute of Technology [Ireland]) and companies (Engie, Siemens and ESB) involved. In order to develop reliable and valid test material, an experienced test development partner (BDO) is a member of the project team. To establish a stable connection with the engineering labour market, the three national engineering federations in Belgium, The Netherlands and Ireland were brought on board (IE-net, KIvI, Engineers Ireland). These federations play an essential role in connecting higher education institutions (HEIs) with a large number of employers that hire engineers. Validation in a wider European network of universities and companies will be tackled by respectively SEFI and FEANI.

1 PROFESSIONAL ROLES IN THE FIELD OF ENGINEERING

1.1 Problem statement

The McKinsey '*Education to Employment*' survey [2], organised with more than 5,300 young people, 2,600 employers, and 700 education providers, shows that only 35% of the employers agree that new graduates are adequately prepared. Interestingly, for education providers, these percentages increase to 74%. Apparently, on the supply side, education institutions believe that they are equipping their students with the necessary skills and competences whereas employers, on the demand side, feel

otherwise. This skills mismatch has become an important topic on the agenda of many policy makers. A focus on transversal skills (e.g. self-management, interpersonal skills, adaptability, communication skills, interpersonal skills) is often put forward as an important way to overcome this skills mismatch.
In the field of engineering education, interpersonal skills, teamwork, communication, and problem solving skills are most frequently identified as highly important by engineers [3-4]. As stipulated by Chan et al. [3], although there is high degree of agreement on the importance of these skills, employers observe a significant gap between expectations and reality.

Apart from the skills mismatch, a number of employers indicated that fresh engineering graduates are unable to identify their strengths and weaknesses during a job interview. It appears that fresh engineering graduates lack the introspective qualities to look at themselves and reflect about the question "*Who am I as a, for example, electrical engineer?*". Answering this question does not only entail a critical self-reflection on one's own thoughts and prior achievements, but also an articulation of one's future aspirations in the engineering profession. The latter aspect presumes a more detailed knowledge of the different professional roles that engineers fulfill in the labour market and which sets of competences are required. For example, in the field of chemical engineering, an R&D engineer may require a completely different set of transversal skills compared to an engineer in a more commercial role.

1.2 Employability: Increasing self-awareness

Employability is often used as a container term without exact definition. In line with Yorke and Knight [5], we endorse three components of employability: (1) increased understanding of academic knowledge, (2) a set of generic skills appropriate to the workplace, and (3) personal attributes (e.g. enthusiasm, flexibility, self-reliance, aspiration, seizing opportunities). As pointed out by Creasy [6] improving employability skills "*requires students to record their achievements and to reflect on these*" (p. 18). The author showed that students find it difficult to articulate their employability skills and that they have problems with writing reflective reviews about themselves and their own assessment of their competencies.

Increasing self-awareness among engineering students requires a high level of metacognitive thinking and the ability to reflect at a higher order level about oneself as a future engineer. Improving metacognition includes helping learners to (1) be more aware of their own implicit beliefs and (2) build a broader sense of purpose behind their learning [7].

1.3 Labour market entry for recently graduated engineers

As stated by Hofland et al. [8], there is a wide variety in career paths for graduated engineers. Going beyond the typical specialist versus management-dichotomy, this diversity is reflected both in terms of disciplinary wealth (e.g. electrical engineering, chemical engineering, civil engineering) and the professional roles that engineers fulfil in a particular organisation (e.g. service engineer, technical sales engineer, production engineer, process engineer…).

An important challenge of the PREFER project is to come up with an integrative framework wherein this multitude of engineering positions is summarized in a manageable and sensible way. Rather than mutually exclusive categories, we argue in favour of a framework wherein engineering positions can be described in overlapping sections if they fit several professional roles.

A similar framework has already been designed for the field of medicine. The CanMEDS framework that identifies and describes the abilities physicians require to effectively meet the health care needs of the people they serve. These abilities are grouped thematically under seven roles [9].

2 PROFESSIONAL ROLES FRAMEWORK

In contrast to the plethora of studies focusing on the essential transversal skills in the field of engineering, research on the classification of the multitude of professional roles that fresh engineering graduates can take on in the labour market is scarce. It is often presumed that all engineering careers are homogenous and require the same balance of technical and transversal skills [10]. Other engineering careers than the stereotypical 'engineering practitioner', for example, researcher, consultant, technical-commercial representative, often receive less attention. In their study, Brunhaver and colleagues [10] discriminate between three engineering roles of a large sample of recently graduated engineers (N=543): manager (15%), engineering consultant (21%) and engineering practitioner (64%). Problem solving and analytical skills were deemed equally important in all three engineering roles. Communication was rated as less important by engineering practitioners than by managers or consultants. Managing uncertainty, business knowledge and leadership were rated significantly higher in importance by engineering managers.

2.1 Business strategy model of Treacy and Wiersema

The business strategy model of Treacy and Wiersema [11] describes three strategic positions that companies can take in the value chain: (1) Operational Excellence (i.e. focus on maximizing efficiency by reducing costs while optimizing quality); (2) Product Leadership (i.e. focus on cutting-edge research & innovation), and (3) Customer Intimacy (i.e. focus on service of client systems and customer satisfaction).

Interestingly, the business strategy model of Treacy and Wiersema can easily be translated into the engineering field. A large-scale analysis of more than 7,500 job vacancies in the field of engineering in the year 2014 [12], showed that each job vacancy could be classified in one of the three categories outlined above: Operational Excellence (46%), Customer Intimacy (30%), and Product Leadership (24%).

2.2 First-year student survey

In the Rolling project [8], the Treacy and Wiersema model was operationalized by means of three fictional engineering job vacancies. A sample of 172 first-year engineering students was asked to indicate which job vacancy they would apply for. In contrast with the outcomes of the large-scale job vacancy analysis, 58% of the first-year students expressed a preference for the Product Leadership role. Thus, there is a very clear discrepancy between the preferred type of jobs of first-year engineering students and the jobs that are available in this category (24%).

In a second stage of the survey, the first-year students were asked to rate their self-perceived mastery levels of the 13 faculty learning outcomes (e.g. problem solving, communication, critical reflection, entrepreneurship, for a comprehensive overview, see [8]). Interestingly, students with a preference for the Operational Excellence vacancy, expressed significantly higher levels of problem solving/analysis and operationalisation compared to the other students. Analogously, students with preference for the Customer Intimacy vacancy rated themselves significantly higher in communication and entrepreneurship. In sum, there seems to be evidence that students tend to be more interested in job vacancies for which they deem themselves to have the required competencies and consider themselves to be good at.

2.3 Company survey

The Treacy and Wiersema model was also presented to a large sample of companies employing engineers (N=121). 91% of the respondents indicated that they recognised the model in their own company. A small proportion (6%) indicated that they needed some adjustments to the model (for example, management was considered missing). In a next stage, respondents were asked to indicate to relative importance of each of the aforementioned learning outcomes for each role. For example, for the Product Leadership role, design and development and specialized technical knowledge were considered to be the most important (for a more detailed overview, see [8]). In general, the company response pattern closely reflects the outcomes of the students' survey.

2.4 Conclusion

The Treacy and Wiersema model seems to be a promising framework to look at the variety of engineering positions. An important objective of the PREFER project is to fine-tune the model and to further tailor it to the engineering domain. Special focus will need to be spent on the specialist versus management dichotomy, a prevailing theme among many young engineers.

3 INTEGRATION INTO THE ENGINEERING CURRICULUM

In the following paragraphs of the paper, we will address how students' employability can be addressed in the engineering curriculum. An extensive search in engineering education literature as well as in literature on the initial path of recent engineering graduates was carried out. Despite higher education institutions' claim to prepare their students for their future career as an engineer, little evidence was found of institutions making a distinction between the different roles a graduate will function in when working as an engineer, and the skills pertinent to such a role. Many of these preparations include the earlier defined transversal skills, next to internships and other activities such as company visits, guest lectures, etc.

In order to limit the scope of this project, it was therefore decided to focus on a number of transversal skills: Entrepreneurial Skills, Innovation Skills, Communication and Networking Skills, Teamwork and Ways of Thinking, and Lifelong Learning. The selection was made based on the 4TU Centre of engineering education's vision on the future of engineering education [13].

3.1 Entrepreneurial Skills

Entrepreneurial skills are defined by Adeyemo as the ability to manage and create an enterprise by having vision and taking initiative and risk [14].

The idea of learning technical and entrepreneurial concepts while solving problems was the goal of a case study and lab experiences introduced in a core mechanical course of a Western private university. The case study comprised a realistic case scenario where engineering and entrepreneurial concepts were taught. Pre and post tests were carried out of students in order to understand if entrepreneurial skills could be implemented in core engineering courses without interfering with the technical skills and if a student's entrepreneurial self-efficacy (based on business confidence) changes with one case study. Results showed that students are able to increase their entrepreneurial skills without decreasing the learning of core engineering competencies and students reported self-efficacy improvement pre-to-post in just one case study [15].

Moreover, business and engineering are bridged by sales education in engineering programs. A department of industrial engineering supported by the university business school and industry partners provided a technical sales course introducing investment economic methods and theory. A pre-post survey of students assessed their interest and learning ability of sales skills. Results as published by Bumbluskaus et al. showed that the course enhanced students' sales skills and increased their desire to pursue a sales career [16].

3.2 Innovation Skills

Benjamin et al. defined innovation as the creation of new and technically feasible ideas or the adaptation of others' ideas [17]. Innovation requires thinking out of the box and an open mind, using creativity and imagination but also the use of logic, analytics and planning. According to Kamp [13] students should be stimulated in innovation by going to new environments with new challenges, and new ways of thinking (e.g. going abroad for studies).

The Engineering School of Los Andes University integrated a 2 semester prototyping course in the third year of the curriculum of System and Computing Engineering in order to improve teamwork and innovation skills. The students present it in periodic written reports and oral presentation, and in a final presentation carried out in an engineering projects fair. Hernandez and Ramírez [18] indicated that students' perception of this course showed that they are aware of the importance of teamwork and innovation for their projects.

The Department of Computer Science and Information Engineering in the National Chung Cheng University of Taiwan created a capstone course which integrates training creativity. This training involves workshops of management techniques provided by managers, of work experiences delivered by alumni and of sustainability and globalisation shared by industry experts. According to Hsiung et al., the results of a project-based learning in combination with creativity training showed enhancement in students' creativity skills [19].

3.3 Communication and Networking Skills

Communication for engineering universities is commonly conceived as oral and written technical skills. However, communication is no longer restricted to oral presentation and written technical reports, but involves interpersonal communication such as listening, compromising, understanding others point-of-view and discussion with others [20]. A study in the field of pharmacy in Finland showed improvement in communication competences by using practical training in real work situations, and feedback and communication between mentors and students [21].

As Kokkonen and Almonkari, we view networking as an interpersonal communication skill because networking is the ability to interconnect with individuals through initiated and maintained communication [20]. As shown by a study of Aerospace Engineering alumni at Delft University of Technology, it is essential to make students aware of the importance of networking and to enhance their networking competences which may open them to future professional opportunities [22].

Donell et al. [23] showed that there appears to be a disparity between the communication situations in the classroom and in the industry. Students are simply not able to switch when they enter a professional environment. In addition, the content of the communication courses may be too limited. Generally, communication courses in engineering curricula consist of a writing and a presenting course but typically do not involve listening exercises, intercultural communication, or observing, interviewing and meeting skills. This does not mean students are not exposed to these skills in project-based education but they are not formally taught. Whether feedback is offered, depends on the individual tutor, rather than this happening in a structured fashion.

3.4 Teamwork and Ways of Thinking

Working in teams is a vital skill in engineering. This was the primary reason it was added to the ABET criteria in 2001 [24]. We define teamwork as being based on collaboratively working in groups to achieve a goal. In teams, engineers are asked not just to think critically (i.e. to ask the right questions to formulate new directions to operate) but also to think interdisciplinarily (i.e. to collaborate and involve other engineering disciplines, humanities and social sciences) [13].

Master students of Aerospace Engineering at TU Delft have the option to attend a Forensic Engineering course which uses real-life based learning. This course consists of lectures and practical exercises, ending with a practical exam where students conduct an investigation and apply the forensic concepts learned during the course to find the cause of the accident. The results of this course show that students developed forensic knowledge, critical thinking skills, standard investigation methodology, hypothesis forming and interviewing [25].

At the University of South Australia, architecture and civil engineering undergraduates in a two-week course tackle a hands-on construction problem. The collaborative work and knowledge interaction between groups of 2 to 4 students of different disciplines, architecture and civil engineering students showed that students increase their multidisciplinary teamwork skills [26].

3.5 Lifelong Learning

Lifelong learning encompasses continuous personal and professional development. In a world full of changes and uncertainty in career paths, “learning how to learn” should be the goal of engineering studies in order to prepare students for constant and continuous learning [13]. To engage lifelong learning skills, the Center for Engineering Learning and Teaching at the University of Washington, provide a course where students are taught to plan their studies, to assess and monitor their learning, and recognise their strengths and weaknesses [27].

Lifelong Learning is becoming a key focus for many industries and governments alike. In order for a person to stay employed in their position they must be able to keep up with technological developments and changes in the way their industry carries out its business. An example is the retraining of the workforce at the Boeing Company for the production of the Boeing 787, Dreamliner. 2D Paper technical drawings were no longer used, only 3D computer models. The aircraft was to be manufactured primarily out of composites rather than aluminium. An intensive retraining schedule was created and successfully implemented [28].

3.6 General observation

Although many institutions eagerly implement transversal skills in their curricula with the aim to better prepare students for the labour market, a simple self-assessment of participants is often the only form of evaluation carried out. No longitudinal studies were found where students were followed in their years after graduation, or other forms of measuring the effectiveness of the skills education. This is an area that deserves serious attention in the opinion of the authors.

4 DISCUSSION

When examining the professional roles in the labour market of engineering graduates, a number of issues should be taken into account.

Firstly, in the 21st century labour market, the calls for interdisciplinarity grow louder and louder. In most cases, engineering graduates are no longer predestined to become part of an exclusive team of highly technical skilled peers but they are more likely to cooperate with colleagues from diverse professional backgrounds. This observation has important consequences for a research project focussing on professional roles of engineering graduates. In some roles, being part of an interdisciplinary team constitutes a fundamental aspect of the content of the role (e.g. project engineer) whereas for other professional roles the interdisciplinary scope is rather limited (e.g. service engineer).

Secondly, we should look at skills training. Previous research has shown that transversal skills are often not that role-specific [27]. They are needed for each role but with different emphasis. Also the effectiveness of skills training is hardly ever investigated beyond the point of self-assessment by the learners. It remains to be proven that exposure to skills training is effective but proving the gaining of skills is an area that has yet to be investigated.

Finally, of a more philosophical nature, we could debate the prime responsibility for a student's employability. Where does the responsibility of engineering education institutions stop and where does the student's responsibility takes over? Personal growth and career development are often considered a 'joint venture' between employer (e.g. through providing training opportunities) and employee (e.g. actively reaching out to new opportunities). For example, Colman and Wilmott [29] showed that 67% of the respondents (N=108) indicate that the development of soft skills for engineering graduates is a joint responsibility for both engineering institutions and students. Only 13% of respondents considered this only to be a responsibility for students. All partners of the PREFER consortium agree that engineering institutions should (1) give a first impetus to students' emerging self-awareness, and (2) contribute to students' empowerment potential for personal and professional growth.

ABSTRACT

There is a growing concern about responsibility of decision makers. Professional and personal life environments are more than ever Volatile, Uncertain, Complex, and Ambiguous. This system paper discusses decision making skills in engineering education along three complementary perspectives: Maths-based, Social-based, and Career-based. This review sketches the premise of a transversal decision skills learning outcomes framework for the continuous enhancement of engineering education programmes around decision making skills, and in line with the evolution of graduate engineering profiles.

Conference Key Areas: Engineering Skills

Keywords: Transversal skills, decision making, engineering and STEM education, learning outcomes.

[1] Corresponding Author: S. Rouvrais, mailto:siegfried.rouvrais@imt-atlantique.fr

INTRODUCTION

Nowadays, the organizational reliability depends on the ability of the actors to organize and reorganize in order to anticipate and cope with unexpected situations, including skills of improvisation, creative bricolage, and attitude of wisdom [1]. The context of this system paper is the growing concern about responsibility of decision makers. The world is more complex, with multiplex of forces and no cause-and-effect chain. Whether they are to act as experts in STEM or other fields, future engineers should be specifically prepared to making decisions in VUCA environments (i.e. Volatile, Uncertain, Complex, and Ambiguous).

How to prepare future engineers to make more reliable decisions in VUCA environments and equip them with decision making skills in formal curricula? This paper first recalls accreditation requirements around decision making in engineering. Along three perspectives of decision-making (DM), it proposes specific learning outcomes applicable for educational programme design or realignments, and presents for each some active or experiential courses to meet relevant skills. The three perspectives considered are (i) Maths-based DM, (ii) Social-based DM, and (iii) Career-based DM. Unified for the three perspectives, the paper then discusses the opportunities of a transversal decision skills learning outcomes framework.

1 PROGRAMME OUTCOMES AND TRANSVERSAL SKILLS

1.1 Accreditation requirements

Decision is not only about knowledge, it is also about skills. Skills relate to the "ability to apply *knowledge* to complete tasks and solve problems. Skills can be described as cognitive (use of logical, intuitive and creative thinking) and practical (involving manual dexterity and the use of methods, materials, tools and instruments)" [2]. The ENAEE, which sets Programme Outcomes for Engineering Education accreditation in EU [3], introduced in 2015 priority in Decision Making and Judgment abilities. From now on, in Europe, the learning process should enable Master Degree graduates to demonstrate:

- ability to manage complex technical or professional activities or projects that can require *new strategic approaches*, taking responsibility for DM;
- ability to *integrate* knowledge and handle complexity, to *formulate* judgements with incomplete or limited information, that include reflecting on social and ethical responsibilities *linked* to the application of their knowledge and judgement.

In the CDIO Syllabus [4], decision analysis with uncertainty (ref. 2.1.4) and initiative and willingness to make decisions in the face of uncertainty (ref. 2.4.1) are requirements for personal and professional skills. Making complex technical decisions with uncertain and incomplete information is also a requirement for exercising judgment and critical reasoning (ref. 4.7.7). The European Qualification Framework, recalls at level 5 "competence to exercise management and supervision in contexts of work or study activities where there is unpredictable change"; and at level 6 "to manage complex technical or professional activities or projects, taking responsibility for DM in unpredictable work or study contexts".

1.2 Multidimensional and transversal Decision Making skills for Education & Training

Judgment skills correlates to DM skills. Psychological explanations describe inaccuracy in forecasting. The central theme is that most people use mental strategies called heuristics to cope with the complexities of making estimates. These heuristics can also lead to systemically biased judgments (e.g. over-optimism). Heuristics could thus lead to erroneous decisions. A new heuristic requires a learning time, if the environment is too volatile, actors will not have resources to mobilize adequate heuristics, leading possibly to dramatic consequences. Complexity can lead to information overload with effects on the DM process. Moreover, uncertainty and ambiguity have consequences on the level of performance. The conditions of VUCA environments strongly affect constraints the decision capacity. Ones has to understand VUCA characteristics and sources, and their effects on DM processes.

The concept of decision has multiple dimensions. For engineers, DM echoes in scientific methods (e.g. Math-based), human environment (e.g. Social-based), or even in professional pathways (e.g. Career-based). DM skills, been learned in one context or to master a special situation, are also transversal (i.e. “skills acquired in one context that, with adaptation, may be applied in another context” [2]). Students are to capture the multiplicity of contextual factors influencing individual and / or collective DM processes.

2 BACKGROUND ON MATHS AND SOCIAL BASED DECISION MAKING SKILLS

2.1 Foundational background: rationality and uncertainty

The giant leap in mathematical approach to DM is arguably in 1202 with the publication of *Liber Abaci* by Fibonacci [5]. The next year hundreds saw great improvements to standardize Decision Methods aimed at calculate future events as an attempt to minimize risk. DM skills from mathematical viewpoint are originated in gambling: the player constantly estimates his/her chances of winning or losing. The field of decision analysis, originally mostly a mathematical discipline, has evolved into a useful method for industry and government. The core of the method is to help decision makers gain a greater understanding of the problems they face, both quantitatively and behaviourally. The expected utility theory, game theory and decision theory are important to understand how politicians and other stakeholders behave under condition of uncertainty and how decision models are constructed. But the limitation of the classical approach to probability in the context of decision theory is that the prediction of the outcome of a single event is based upon events that have already occurred, based on empirical evidence. However most decisions are disposed to the uncertainty of events that have not yet materialized. Expected value (or, where appropriate, utility) is the metric value of decision theory. The highest (or lowest if the assessment is cost related) expected value of a decision process is the best option in a portfolio of options, when all possible outcomes have been accounted for, with weights (probabilities) indicating the chance of occurrence (uncertainty).

People are not always rational and they do not always think about maximizing their own interests. Taleb [6] claims that the fundamentals of using probability distributions for estimating the impact of events on outcomes are idiosyncratic. This leads to what Taleb calls ludic fallacy for explaining the drawbacks of using the basic axioms of probability to estimate future uncertainty. Students are to understand the scope and limitations of mathematical decision-making methods and of computing tools.

2.2 Irrationality and VUCA contexts: reliability

There is no simple explanation for decision which seem sometimes irrational. There are limits to the cognitive and information-processing capacity we can devote to any judgement. Technical explanations cover inaccuracy in terms of project uncertainty, unreliable or out-dated data and the use of inappropriate forecasting models [7]. If sociological factors play a role, it is only a limited role. Both perspectives (economic and psychology) also focus on individual behaviour rather than social processes. However, sociological forces interact with psychological forces and will affect individual behaviour if groups act without any clear coordinating mechanism. In reality, on the interactions between individuals and groups in a social learning context, group forces and group motives are important, reflecting not only conformism, social imitation or conscious identification with group but also group-centred goals and behaviour.

The most fundamental capability of human beings is arguably conscious decision-making. Such decisions are made in non-emergency situations but often under a high degree of uncertainty (where uncertainty can be defined as the subject's conscious lack of knowledge about an object which is not yet clearly defined, in a context requiring action for decision). But in VUCA contexts, dynamicity and emergency are in the place. Mechanisms to detect early signs of crisis and react early enough are required. This point is a key element of High Reliable Organizations (HRO) [8] which seeks to understand the normal functioning of human-based decision systems by identifying the characteristics of HRO and explaining their exceptional performance. To reach a higher level of reliability, Roberts recommends flexibility in the decision-making process. Weick [1] identifies three characteristics of HRO in contexts where the error is unforgivable: information overload, constant turbulence, and increasing complexity. Unlike other theoretical frameworks on reliability (e.g. Theory of Normal Accidents), the HRO and Actionnist currents have even the specificity to consider human behaviours as a source of reliability rather than failure. These organizations are able to create and maintain a state of collective watchfulness thanks to the quality of the interactions between their members [9]. Weick mentioned that respectful interactions, a system of roles, improvisation, and watchfulness are the four sources of reliability. A work on VUCA conditions from this theoretical works is supposed to answer the limits faced by maths-based decision making methods. The authors suggest to use this approaches which take into account VUCA parameters, as active learning courses.

3 LEARNING ACTIVITIES

3.1 Active learning activities

As course examples, In France, ESSEC Business School created the MOOC "*L'avenir de la decision : connaître et agir en complexité*" (Edgar Morin chair, https://fr.coursera.org/learn/lavenir-de-la-decision), composed of videos and lectures, including knowledge oriented courses. Aside, student may learn from real experiences, to develop and reinforce their decision competencies. In another context, in Spain, there are on-line university courses in decision engineering such as that given by the Rey Juan Carlos University of Madrid [10], to learn to make the best decisions with less time and to analyse them in a globalized world. With these courses, students are expected to improve the quality of decisions taken and, consequently, improve the results of decisions.

Various pedagogical models exist to foster collaborative dimensions and practical skills in formal STEM curricula (e.g. Problem-based learning, project-based learning).

In formal curriculum, the Disaster Week, initiated at Reykjavik University [11], exposes students to real-life engineering, as a multidisciplinary introductory course. With one week of team work, students are to develop an action plan for dealing with an unforeseen event of some complexity, demanding DM, fast based on incomplete information. Topic includes a natural disaster, e.g. a potentially devastating epidemic in Iceland or a volcanic eruption with the lava flow towards the city. This style of learning enforces the importance of teamwork, the need to gather information quickly, and one has to make decisions fast based on incomplete information. It permits to meet intended learning outcomes for freshmen around Maths-based DM.

At IMT Atlantique, French graduate engineering school, the Springfield serious game exposes students to real cases in order to show the complexity of actions and decisions in risky situation. The context is an accident which occurred in a nuclear plant. Each player has a specific role, with specific objectives and information (a plant manager, a safety engineer, and operators). Players have to work together in order to save the plants. In debriefings, students explain their behaviour and decisions.

3.2 Towards experiential learning activities

Future graduates are to be able to turn knowledge into skills, especially in DM. The complete development of a competence is better covered by various integrated learning activities, including real experiences or work-based learning models. For DM skills, in all its dimensions, experiential and cooperative learning is the key for Teaching & Learning innovation. Some courses permit to show by experience that DM is a complex process, particularly when the decision leads to irreversible consequences.

Still at IMT Atlantique, an inter-semester course (2 ECTS) trains students to take decisions and react in unexpected and unpredictable situations [12]. Using an experiential learning model as proposed in the French Naval Academy, the one week course has some outdoor elements in the sea environment for novices. The real experiential situations so selected reflect nautical risk scenarios with levels of complexity and time pressure (including Man Over Board exercises, cf. Figure 1), where specific decision skills are to be acquired or reinforced, such as risk and priority management, watchfulness, team management with respectful interactions, judgement and responsibility, etc. Participants also have to prepare a navigation (weather, equipment, refuelling, practical information), plan the stages, estimate the navigation times, the possible risks and dangers, prepare the most delicate passages, prepare fall-back solutions and identify success factors. Just like a project, the success of a sailing cruise requires a certain number of technical and human skills. In these real situations, flexibility constitutes the sources of reliability and performance. These in-context experiences are to be useful in an engineer career where responsibilities increase (e.g. decision-makers to face complexity, uncertainty and urgency). A first experience, as a non-expert from the environment, may create a learning-loop for future work-based situations including improvisation [1].

The experiential scenarios proposed rely on theoretical frameworks dealing with reliability. They use the four sources of reliability as assessment criteria and include situations with a high level of complexity, uncertainty, and time pressure that future decision makers are supposed to face in their future professional activities. As learning outcomes, the learning process should enable graduates:

- to tackle moral, ethical, and social issues of a situation;
- to identify sources of uncertainty, face complexity and continuously recognize and qualify the criticality of a situation, inc. its events and factors;

- to accept uncertainty, fix priorities and formulate judgment on situational events individually and collectively;
- to react flexibly to events and regularly assess the weight of an error in the DM process;
- to take initiative and responsibility on choices and actions during the situation, and reflect from experiences in order to increase resilience.

In [12], empirical evidence on motivational factors have been first analysed qualitatively. Based on direct observations and experiences, quantitative analysis is under investigation to determine how to better prepare future engineers to make more reliable decisions in VUCA environments. One's and team's DM skills are thus formalized in program components, as transversal, with aforementioned learning outcomes and VUCA-based progressive proficiency levels. Design-based research methodology is also under consideration in order to conceptualize experiential learning activities and iteratively analyse learner achievement and program coherency and framing.

Fig. 1. Collective urgent rescue.

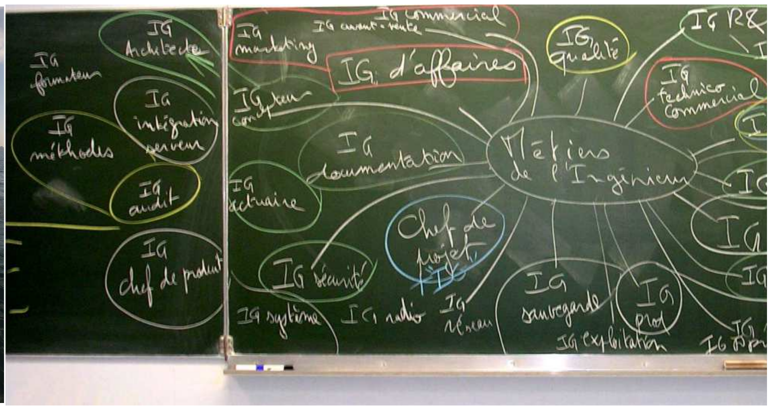

Fig. 2. Job map, from [14].

4 CAREER BASED DECISION MAKING SKILLS

Investigations on courses including progressive VUCA circumstances should also facilitate the integration and career paths of young engineers in their professional life and workplace. Engineer diplomas greatly facilitate first job offers and open up on broad career possibilities in many economic fields where engineers may often exercise their potential as leaders and future decision makers. However, uncertainty and indecision often result from student appraisal of the career kaleidoscope. Some struggle to identify career directions and therefore need some time before feeling committed and being operational within their curriculum and first jobs. The European Lifelong Guidance Policy Network (http://www.elgpn.eu/) regards career management skills as competencies which help individuals to identify their existing skills, develop career learning goals and take action to enhance their careers.

It is thus critical to reinforce students' self-confidence, especially when considering that the recruitment market is becoming more and more demanding and competitive for newly graduated engineers. Students' perception of a profession can strongly influence their career choices. In addition, yet many students who have had only limited exposure to a profession may base their decisions on limited or distorted perspectives, for example a single internship or co-op experience, both positive and negative [13].

It is essential to provide students with means which will enable them to participate actively in their own learning and develop a long-term aspiration for future career paths. As learning outcomes, the learning process should enable graduates:

- to know oneself and analyse his/her set of skills;
- to gather information, identify options, and explore career options;
- to recognize and define one's choices;
- to define career paths, to plan and evaluate them, to select options;
- to gain flexibility and propose a coherent professional project inc. career orientation, and to combine personal development therewith.

Traditionally, educational institutions design career preparation programs which focus on making their students more attractive to potential employers. As example, in a University context, the Department of Guidance and Professional Insertion of the Foundation University-Enterprise of the Balearic Islands has realized the Occupational Guidance and Occupational Assistance Program. This non-compulsory program aims to guide and improve the possibilities of self-employment of the university graduates and students who are seeking employment. Concretely, it permits to improve employment opportunities by designing a personalized itinerary for job placement. This personalized itinerary consists in the realization of individualized sessions of professional orientation: how to properly take decisions to get a job, how to apply for a job interview to get an employment. Students learn the ability to make the right decisions from the individualized orientation sessions. At IMT Atlantique, a compulsory 63h career preparation course is in place since 2007, to disclose to students, via active workshops over three years, their career perspectives, enable them to participate actively in their own learning path, to build their future professional identity, and to plan proactively their future career [14], in VUCA workplace contexts.

5 SUMMARY AND ACKNOWLEDGMENTS

In a rapidly changing world, the VUCA context requires now to rethink the vision for engineering education [15]. As seen today in the European society, the nature and dynamics of change creates unpredictability and future engineers are to manage complex situations with critical reasoning. Professional life environments are more than ever VUCA. This context makes decisions even more strategically critical. To prepare future engineers to make more reliable decisions in VUCA environments best benefit from experiential learning models, progressively all along a curricula, with a transversal skills approach. As Le Boterf defends it [16], a skill is only effective once it has been tested and validated thanks to its confrontation to reality. This system paper tends to thus support the coherent inclusion of active and engaging pedagogical models, with DM as a transversal skill, in association with three complementary and unified perspectives including learning outcomes:

- Maths-based DM, with rationality;
- Social-based DM, including people's interdependencies and social identities;
- Career-based DM, according to own career path.

A dedicated decision framework is to provide support for faculty staff to improve student competence in decision skills, interwoven with the learning of disciplinary knowledge and its application in professional environments. Mastering of these skills is to be assessed by various stages of complexity, e.g. partial application, realisation, adaptation to various VUCA situations, and anticipation. Societal responsibilities are elements of DM and included in the three aforementioned perspectives. In fact, good decisions rely on many factors, context-dependant. The DM learning outcomes are to be indicated to provide a pragmatic guide to deal with the pressing ethical and social considerations. The aim is to ensure that students are educated, trained, and empowered to prioritize ethical and social considerations in their decisions, diminishing negative consequences in their future work, professional itinerary, and personal life.

The authors would like to acknowledge their colleagues from IMT Atlantique (French graduate Engineering School), Ecole Navale (French Naval Academy), Reykjavik University (Icelandic Engineering School), the Department of the Guidance and Professional Insertion at *Fundació Universitat-Empresa de les Illes Balears* (Spain), City of Glasgow College (VET School in Scotland), the Scottish Credit and Qualifications Framework Partnership in Glasgow, and the *Fondation des Régions Européennes pour la Recherche, l'Éducation et la Formation*, who oriented the perspectives defended in this paper.

ABSTRACT

Innovations are a prerequisite for enterprises in order to be successful and competitive in fastly developing markets demanding interdisciplinary development of complex products. The education of engineers in universities has to enable them to deal with these challenges and growing international cooperation in most business areas.

A consortium of three universities of applied sciences (UAS) from Finland, the Netherlands and Germany has agreed to advance their curricula by these demands and to set up an international collaboration of a group of universities and companies to educate students in projects that teach them how to develop innovation in collaboration with companies.

This paper describes theoretical background, the setup and the planning process of this project.

Conference Key Areas: Engineering Education Research, Curriculum Development, Continuing Engineering Education and Lifelong Learning

1 INTRODUCTION

Actual and future markets in a globalized world challenging companies in all fields of technology are developing their portfolio fastly. Therefore innovations (= new and economically successful products [1]) are a prerequisite for enterprises in order to be successful and competitive in these markets. Furthermore most products require the interdisciplinary combination of e.g. mechanical, electronical and software components. Companies not only have to know their area of expertise but also to be able to adopt quickly to a changing environment, open up new markets as intrapreneurs (= persons working within the company having entrepreneurial capabilities) and possibly developing lead innovations worldwide.

These tasks challenge the Innovative, Interdisciplinary, International, Intrapreneurial and Interpersonal (= $\mathbf{i^5}$) skills of engineers and universities of applied sciences have to be able to educate especially engineers to fulfil these requirements. Engineers have to be able to command the entire chain from the first idea up to the product in the market. This chain includes product development, production and marketing.

When observing the curricula of engineering education within Europe, it can be seen that this kind of skills hardly, or not in coherence to each other, is implemented. A consortium of universities of applied sciences (UAS) from Finland, the Netherlands and Germany has been setup to get more experiences implementing these aptitudes in their curricula. Starting graduates are being positioned in key roles in SMEs and there they can help Companies to develop meaningful innovations. UAS (universities of applied sciences) therefore need to decide to adopt in their curricula i^5-competencies to these needs and to set up an international collaboration of a group of universities and companies to educate students in projects that teach them how to develop innovation in collaboration with companies.

The basic idea is to set up a mixed group of students from all three UAS, give them an innovative development task from a company. This is important especially in the case when the graduated engineer is employed in a small and medium sized enterprise and in the case when the young engineer creates his/her own company. In bigger companies there is always need to find new managerial potential to be trained for higher management. The first implementation of the setup is planned in spring 2018.

This paper describes theoretical background, the setup and the planning process of international design projects in cooperation with companies, their allocation in the bachelor programs of mechanical engineering at the Universities of Applied Sciences in Oulu, Eindhoven and Ulm. Experiences in planning process and consequences will be drawn up for future education of engineers.

2 THEORETICAL FOUNDATION

Outstanding Mechanical Engineers are essential for enterprises in order to develop new and successful products for actual and future markets. Thus universities all over the world are challenged by industry´s demand for ideally ready-for-practice engineers coming out of study programmes and to orient their study programmes on the actual needs of industry in the area. Curricula have to be extended beyond deep knowledge of “the fundamentals” of professional engineering and the ability to apply it in practice that is taken for granted by most employers.

These requirements have also influenced accreditation criteria, thus study programs in mechanical engineering should ensure, that students “apply principles of engineering, basic science, and mathematics …; to model, analyze, design, and realize physical systems, components or processes; and prepare students to work professionally in either thermal or mechanical systems while requiring topics in each area” [2].

After finishing mechanical engineering programs, students must be able to work professionally in an engineering environment and to “identify, formulate and solve engineering problems” under typical boundary conditions and to apply and extend their knowledge independently [2].

To fulfil these criteria, professional engineers ideally should have an “entrepreneurial” spirit and some skills beyond pure technical knowledge, here described as the i^5 skills based on Geraedts [3], Fig. 1. The authors therefore aim at integrating these skills into their study programs.

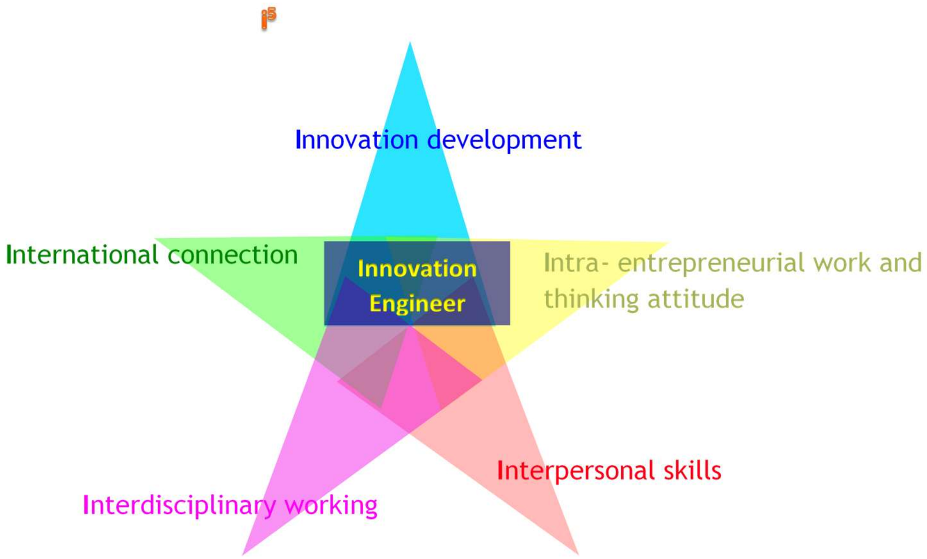

Fig. 1. i^5 – Approach [3]

- The development of **innovative** products deserves that mechanical engineers must acquire basic knowledge about patents as well as methodological approaches in developing innovative products. The importance of these abilities is stressed intensively in literature [4], [5], [6]. This ability is strengthened by project tasks that are based on largely untackled problems taken out of the “real world”.
- Entrepreneurship is important both for the development of national economies and for career of young engineers. Entrepreneurial thinking is not only important for founding new companies but also for the long-term development of existing companies, here called "**Intrapreneurship**". Nevertheless, entrepreneurship as “process of transmitting entrepreneurial knowledge and skills to students to help them exploit a business opportunity” [7] it is rather rarely taught in engineering programs. There are approaches to add this knowledge by extra-curricular activities [8] Expanding lectures by teaching basic questions of company foundation, project tasks requesting parts of it like setting up a business plan, visiting fairs, presenting ideas to potential sponsors or even providing a business

incubator as a university are possible targets of projects in engineering programs.

- **Interpersonal** skills include advanced knowledge about communication within teams, companies or towards customers and public, team leadership and other skills needed for successful implementation of complex projects [9]. Engineers have to be able to arrange duties and to ensure their performance, to create an open minded atmosphere within the teams, to recognise and improve their strengths and weaknesses and to cope with conflicts. Methodical competences particularly include the ability to recognise and analyse technical problems, to plan a way to solve problems, find an adequate solution and to reflect the chosen approach critically. They can be encouraged by setting up a realistic and challenging environment for student projects e.g. in cooperation with companies.
- Modern technologies are typically **interdisciplinary** and involve the combination of knowledge and technologies from diverse disciplines. Engineers must be able to determine the interfaces between their area of expertise and other disciplines and to define these interfaces, their interdependencies and their mutual requirements. Therefor they must have a basic knowledge of neighbouring disciplines, to be able to understand project partners from other disciplines and to communicate successfully with each other. Project tasks for mechanical engineering students should include aspects of other disciplines like economy, software engineering, electronics or even ethical or social disciplines.
- In an increasingly globalized economic world engineers need **international** experiences to be able to communicate with customers and project partners all over the world. This requires not only to improve language skills but also to support students in gathering intercultural knowledge and the ability to cooperate in international teams or internationally distributed projects. The most effective way of obtain this experience is working in foreign countries, which is difficult to generally integrate into study programmes. Alternatively an increasing number of universities launch “internationalization at home” as a substitute by lecturing in foreign languages (preferably English), inviting guest teachers from foreign countries or involving international students in their study programs. The approach of the project described in this article is to or organize international projects in cooperation with partner universities or companies from other countries.

Based on these foundation, the partner universities decided to set up a collaborative student project that is targeting at teaching students the i^5- skills.

3 OBJECTIVES OF THE PROJECT

The collaborating universities started cooperating in exchange programs a couple of years ago and are regularly comparing their educational approaches and their study programs. They realised, that several objectives support the needs of all partner universities and partner countries. From the point of view of universities, goals are:

Educational objectives:

- Enhanced curricula with a focus on i^5
- Implement innovation and entrepreneurship oriented education
- Evaluate new ways of teaching in universities
- Strengthened education oriented on the actual needs of industry in the area
- “Internationalisation at home” as an enabler for international experience for students

Collaborative objectives

- Increase the number of students and staff involved in international activities and mobilities
- Anvance existing cooperations between universities, companies and institutions
- Improve the qualitiy of interantional collaboration between universities and companies
- Demonstrate new ways of collaboration between companies and increase and internationalise cooperation with companies of different sectors and sizes
- Include company staff in international activities

Entrepreneurial objectives

- Encourage and enable students to innovate and achieve patentable ideas
- Encourage students to start entrepreneurial activities
- Strengthen intrapreneurial abilities of students and within universities

Industrial and organisation partners target at **collaborational objectives**

- Lower the barrier of SMEs to start collaboration with universities
- Start sustainable collaboration between universities and companies
- Aim at high quality of collaboration between companies and universities
- Build up international contacts and collaboration to universities and companies
- Support sustainable innovation activities in SMEs
- Support entrepreneurial companies in expanding their portfolio
- Strengthen intrapreneurial abilities within companies
- Recruitement of talented students
- Learn from quality-assured systematic innovation projects how to improve the development process within the company
- Facilitate innovative ideas for the development of the company
- Build up connection to universities and to expert knowledge
- Achieve patentable ideas and competitive advantages

Prior to this project, OUAS (Oulu University of Applied Sciences) and FUAS (Fontys University of Applied Sciences) have executed, just the two of them, several project where students have searched for an idea, created a concept, realized the design and built the prototypes. The student groups have been a combination of students from both universities. In that project, the students have not made proper business scrutiny. In the project of this research, the idea is to widen the work to cover preparing to the production and marketing, as well. Also, the financing of the entire product process will be taken into account. The project group will not only be students from different universities, but from different disciplines as well. The guidance of the project will be performed by university teachers together with the professionals from businesses. In this way, students will reach a feeling of real business and entrepreneurship. Along the project, the students can experience the holistic chain from the search of an idea up to the market. They learn also how to work internationally. In this connection the communication in the working group and in meetings is one big subject and use of digital communication technology as well. It is not only technology they learn but also how to work professionally with people who have been educated in different countries in different sectors like in business and technology as well as in different methods.
Because the length of the project will be three years, it is possible to follow the whole chain. After this kind of experience, students are more ready to take a responsible position in a company having own products. The position of product manager is especially suitable for an engineer possessing this kind of special education.

4 SETUP OF THE PROJECT

Based upon the objectives of the project, the project partners decided to set up a project-based learning environment to allow the successful integration of **i⁵** key competencies in undergraduate courses for engineering design students. The setup of the project is shown in Fig. 2.

The general aim of the project is to create a model to realize engineering and business education into the direction of innovations and entrepreneurship in technology sector together with enterprises. Thus each partner university cooperates with 2 companies to ensure close contact to industrial practice and a real entrepreneurial environment where students work in real development projects together with employees from businesses.

The main task of these participating industrial partners is to offer project ideas and to accompany the students during the solution phase to bring in a realistic environment. The project setup is completed by institutional partners like the chamber of commerce and a patent office to add information about the handling of innovations and chances of entrepreneurs.

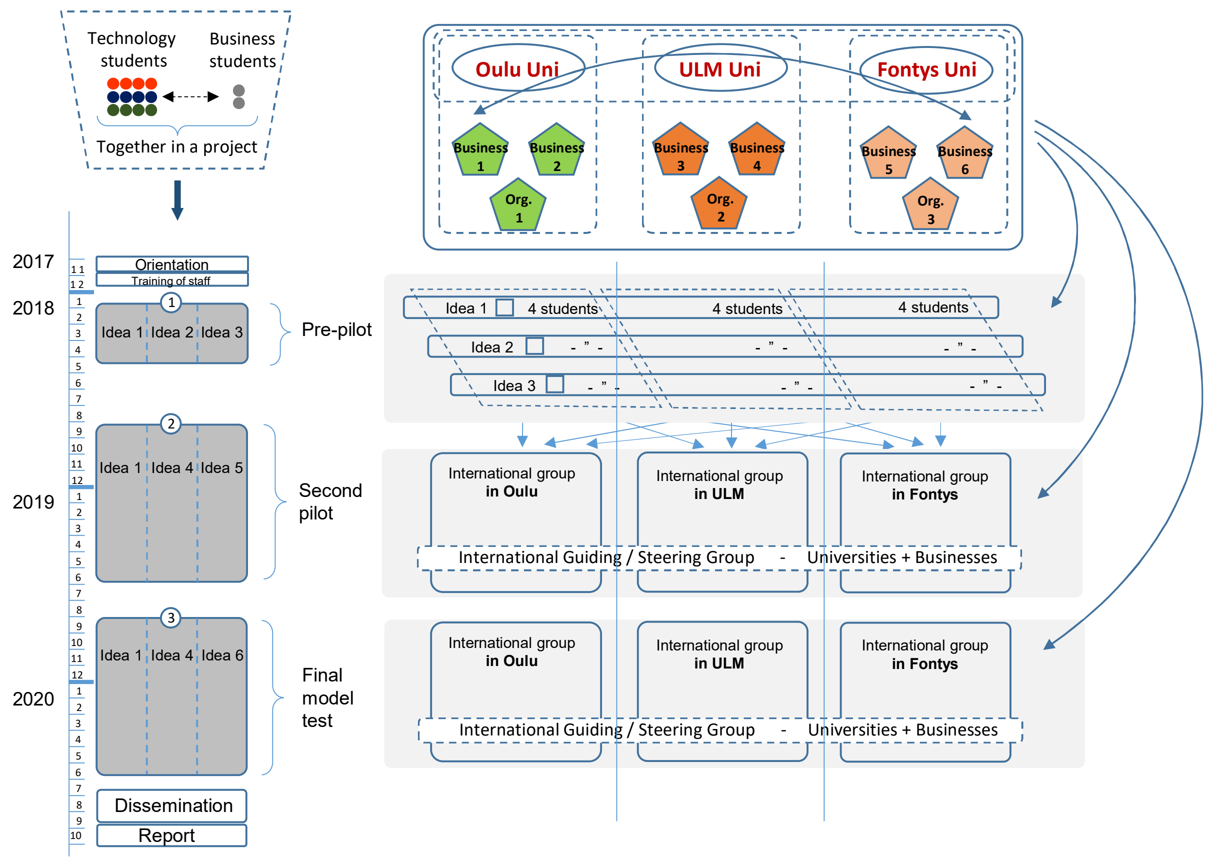

Fig. 2. Project setup

The project is carried out in technically oriented study programs, but will involve business students in all universities as well. The students will be organised in groups of 12 students from all 3 countries (4 from each country) and therefore have to cooperate in an international environment and to handle distributed product development. Their task is to solve a problem from a basic idea of a solution to prototypes and if it comes up along the development process that the idea is on the way to real market the development work will be continued as far as it is possible in the time limits of a student project. The idea is to start shorter projects that can be solved within one round of the project and more complex tasks that need to be handed over to other group(s) in following project rounds to complete it. An idea can be also students' own, so that they will be supported by an industrial partner and institutions to develop their idea towards a real market. It is one goal of the setup of three project rounds to find out what kind of framework is most valuable for the students.

The development projects start with kick-off-meeting of all students and representatives of companies and institutions in one of the partner countries. Students can choose an idea that will be formed to a concept that is worth to develop further. They can form their teams, clarify open questions, make up a time plan and share the tasks and then continue the design work in their home universities and continue a virtual collaboration using digital media.

It is planned to involve not only technical students, but also business students to develop a business model around the coming product, conduct a survey about the market situation, clarify economical demands or the profitability of the product. All the actions on the way from the idea to the market will be identified and evaluated from economical point of view. This examination supports the technical product development decisions as well. Additionally, the business students analyse different financing possibilities that are available to realize the total innovation process up to market. This total view teaches technical students to understand the economic framework of innovation and business students to understand the technical problems on the way form an idea to a product.

During the project students also gain experience in working in international multicultural groups by guidance of business professionals. The result of the development work will be presented and professionals make an evaluation on it. Performance of students will be assessed and grades will be given regarding these evaluation. Students will be asked to write learning diaries to collect their experiences and evaluations of learning during the project.

Teachers of universities and representatives of companies will make evaluation about the project from an educational point of view. This will help to improve the project setup after the first pilot phase. Based on that an improved model to realize the next student project PILOT 2 will be done. At the moment it is planned to carry out 3 pilot phases and then transfer the experiences into a final model to be used in continuous practice in the partner universities.

5 CONCLUSION

This contribution describes the idea, the theoretical background and the planning of an international and interdisciplinary educational development project carried out by 3 European universities. The main idea is to integrate students of universities from different countries and to give them an innovative development task provided by industrial partners to create a realistic environment. In the next step, the idea will be implemented and results will be presented in future conferences.

ABSTRACT

The literature on the management of innovation has strongly emphasised the need for a complex and wide set of competences to successfully manage technological innovation within companies. This paper provides eight years of experience teaching industrial engineers how to integrate technical and non-technical skills in the management of technological innovation. The paper presents the experience of a design based learning course for industrial engineers concerning the New Product Development (NPD) process. The course has been offered to around 400 master students. As an initial result, the paper proposes a model for designing courses on innovation and new product development, useful for engineering schools. In addition, our study suggests that design based learning (DBL) seems to be effective for developing the ability to integrate technical engineering and non-engineering skills, and for developing professional "soft" skills, as well. The DBL approach seems to be less effective for supporting the specialisation of technical competences.

The literature on the management of innovation has strongly emphasised the need for a complex and wide set of competences for successfully managing technological innovation within companies [1] [2]. In fact, along the innovation funnel, several competences, other than engineering ones, become critical: managerial, organisational, and relational competences are especially relevant. This is also confirmed by the many empirical studies that bring into evidence that the high failure rate of technology-based start-ups is mainly due to a lack of managerial competencies, rather than to a lack of financial resources or technical competences [3].

A way to face the problem is to provide engineers with the necessary skills to effectively communicate with other people. At times, this has been interpreted as the need to introduce “soft” skills, and/or “professional” skills [4; 5; 6]. We argue that some of the complementary skills necessary to engineers to successfully manage technological innovation are not only the “soft” or “professional” ones. Engineers also need the “hard” skills related to economic, financial, organisational and marketing matters. This paper provides eight years of teaching experience aimed at providing industrial engineers with the tools needed to integrate technical and non-technical skills in the management of technological innovation.

Starting from an analysis of the innovation process within companies –called the “innovation funnel”- the set of competences necessary in each phase of the funnel was identified. Then, in coherence with the results of this study, a program was defined for teaching the management of innovation to engineers, not only in terms of topics to be introduced, but also in terms of teaching methodology. Active learning was considered the best way to ensure the actual integration of technical and non-technical competences. It is not simply a matter of juxtaposition of competences, but of integration [7]. Students were asked to generate an idea for re-designing an existing product and to actually design the development, manufacturing and commercialisation phases of the innovation process. They were also asked to present and discuss their work with a committee of external experts who were able to evaluate the industrial feasibility and quality of their projects.

The paper explores the results achieved by around 400 students involved in the program whose work was evaluated by external experts in terms of real ability to integrate technical and non-technical skills.

The paper is structured as follows: section 1 gives the theoretical background; section 2 clarifies the research question and the context of the study; section 3 describes and discusses the study results; section 4 gives some final conclusions.

1. THEORETICAL BACKGROUND

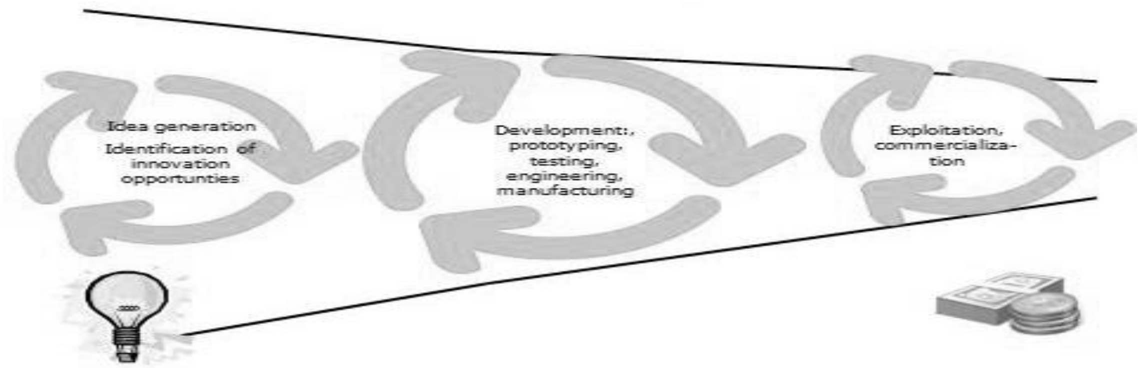
The theoretical background of this paper relies on two fields of study. Research on the management of innovation was investigated in order to define the set of competences needed by engineers in order to successfully contribute to innovation processes. Research on active learning is the reference for defining the methodology of the teaching program.

1.1. Innovation as a managerial process

Technology innovation as a managerial process can be dated back to the ‘80s and ‘90s, when innovation started to be considered an endogenous variable for companies. Before that, in neoclassical economics and traditional industrial economics, technological innovation was mainly conceived of as an exogenous variable. As a result, managerial problems were related mainly to internal R&D

efficiency and information gathering. During the '80s, within the evolutionary economics approach [8], and especially in the ‘90s, within the resource-based [9] and the competence-based approaches [10], technology innovation became a managerial process that needed to be properly managed in order to support a company’s long-term success. This literature also brings into evidence the relevance, for both the individual and the organization, of how learning, competences and skills are fundamental determinants of innovation.
In its Oslo Manual [11], the OECD defines innovation as “the implementation of a new or significantly improved product (good or service), or process, a new marketing method, or a new organisational, method in business practices, workplace organisation or external relations.” It describes innovation activities as “all scientific, technological, organisational, financial and commercial steps which actually, or are intended to, lead to the implementation of innovations.” It is thus evident that the management of innovation requires a wide set of competences.
Moving from a general definition, technology innovation within companies can be represented by the innovation funnel [12] shown in figure 1.

Figure 1. The innovation funnel [12]



.

The innovation funnel includes a phase of investigation of new ideas and technological opportunities, after which the development of an innovative product and/or process and/or service is developed. All along the funnel there is a selection process, according to which ideas and opportunities are gradually screened and selected according to strategic, technical and economic criteria. For many reasons, the innovation funnel takes specific characteristics. So, its slope, total duration and the specific activities conducted in each phase can change significantly.
It is important for companies to be able to properly manage the whole funnel, as the return of all the investments are actually achieved at the end of the funnel, when something new is commercialised. Certainly, technical competences that focus on the specific object of innovation are necessary to successfully manage the innovation process, but they are not sufficient. In order to draw economic benefits from innovation, creativity, problem-solving, economic and managerial skills, marketing know-how and tools are fundamental as well [1].

1.2. Active learning for the management of innovation

Teaching innovation is not only a matter of contents, but also of methods. The literature proposes even the concept of Innovation Pedagogy, a learning approach based upon constructivism that “utilizes academic staff innovation competences and ensures students’ active involvement in innovation processes” [23]. According to innovation pedagogy, active involvement of students is necessary to link academic skills to practice. Reflections on the methods for teaching innovation also come from the field on entrepreneurship learning [24; 25]. This stream of literature confirms the need for active learning in order to "train individuals to act entrepreneurially" [24]. In particular, teaching innovation and entrepreneurship to engineers poses the problem of providing them with the necessary business and cross-disciplinary skills, especially in a global competitive context [25]. And that requires a balanced learning approach including classes as well as exercises, fieldworks, involvement in actual projects. Active learning refers to all teaching approaches in which students are directly engaged in learning activities [13], including problem- and project-based learning [14]. Active learning is recognised to be particularly relevant for supporting the acquisition of skills such as team working, conflict management, problem-solving, communication, and coordination [15] [16]. Within the several approaches to active learning, Problem-Based Learning (PBL) stimulates the acquisition of inquiry skills and the integration of theoretical knowledge by engaging students in solving ill-defined, open-ended, interdisciplinary problems [14] [17]. Among PBL approaches, in DBL students are involved in a project-planning process, in which they are assigned the task to develop an end product, an object. Such an involvement is thus characterised by the six features described by Wijnen [18]: professionalization, activation, co-operation, creativity, integration, and multi-disciplinarity. DBL is an active learning method in which "students gather and apply knowledge while designing creative and innovative practical solutions" ([17]. All the characteristics described above make DBL especially suitable for teaching the management of innovation to engineers. Indeed, DBL allows for achieving and integrating interdisciplinary competences, of both the technical and non-technical sorts.

2. RESEARCH QUESTION AND CONTEXT OF THE STUDY

2.1. Research question

Starting from the premises drawn from the literature with regards to the multidisciplinarity of innovation management and the suitability of design based learning for such a topic, the research question becomes: how can a course on the management of innovation for engineers be designed? Two sub-questions arise: How to identify the appropriate set of competences? and How to design a learning method able to foster the integration of the required technical and non-technical skills?

2.2. Context of the study: the course on Industrial Design

The questions were studied in the context of a course for graduate students in industrial engineering, which was designed and launched in 2007 at University Cattaneo in Italy and monitored over an eight year period. The course is dedicated to a specific type of innovation: NPD [19] and it is labelled "Industrial Design". It is held within a master program on Industrial Engineering and it is offered to interested graduates in industrial engineering, or any technical engineering field (bio-medical, mechanical, electronic, etc.). NPD is the process that leads to the commercial launch of a new or improved product onto the market. The course is thus aimed at teaching students how to successfully identify an idea for a new (or improved) product and how to manage it until its launch onto the market. It is given at the end of the master program and thus provides students with the opportunity to exploit all the competencies acquired in their previous courses and to integrate them with those specifically concerned with innovation management, having a strong practical focus.

2.3. Course design: competencies

To identify the set of competencies needed by engineers to manage the innovation process, we started from the innovation funnel and the related activities, with specific reference to the NPD process. In coherence with Eppinger and Ulrich [19], the funnel of the NPD process can be conceived as composed of four main phases: concept development, product design, process design, and commercialisation.

The early phases of the NPD process are concerned with idea and concept generation. In this part of the funnel the market and the competitive environment are investigated in order to identify potential unsatisfied needs. The technological environment is also investigated, in order to identify technological innovations and trends potentially useful for market needs. In coherence with the market and technology investigation, a first tentative design of the new product is put forward, which is then tested and experimented by means of models or prototypes. The commercialisation of the new product should also be conceived in terms of target pricing and distribution channels, as these strongly influence the product and process design phases. After the concept design phase, the phase of development includes the engineering and the manufacturing phases, i.e, product design and process design. In the product design phase, the product's architecture, components and subsystems are defined, together with the final assembly scheme. Simultaneously, suppliers are identified and cost analysis is conducted. In the process design phase, the tools and machineries to be used in the production process are defined, together with the procedures for quality assurance and process control. As the NPD process should generate value for the company, a Business Plan of the whole initiative must be provided to decision makers, who must synthesise not only the main features of the products, but also its impact on the company’s revenues and costs. This certainly influences the definition of price, and of all the costs of the manufacturing and commercialisation processes. The various phases of the NPD process are not strictly sequential: the concurrent engineering approach suggests, whenever possible, to conduct them partially in parallel, in order to exploit feedback throughout the different stages and anticipate problems.

The set of competencies necessary for the NPD process are synthesised in table 1. As can be seen, the course of Industrial Design was organised in four sets of contents: concept development, product design, process design, business plan.

Table 1. The NPD process phases and the related competences

Phases of the NPD process competencies	**Concept development**	**Product design**	**Process design**	**Business plan**
Technical engineering competencies	Technical know-how about the specific product; product modelling; prototyping;	Technical know-how about the specific product (materials and functionality); manufacturing technologies, assembly issues;	Technical know-how about the specific product; manufacturing technologies, assembly issues; quality issue; control issues;	Technical know-how about the specific product;

Technical non engineering competencies	Competitive environment strategic analysis; technology intelligence; marketing	Cost analysis; management accounting; supplier evaluation; purchasing	Cost analysis; management accounting; manufacturing organisational issues;	Financial accounting; marketing; management accounting;
Professional and soft skills	Creativity; awareness of the external environment	Awareness of the external environment; coordination	Coordination;	Communication; coordination; awareness of the external environment

2.4. Course design: learning methodology

An active learning approach is adopted in order to favour the actual integration of all the competencies necessary in NPD. In particular, a design based learning approach is adopted, in which students are actually engaged in solving an ill-defined problem by designing something new. In the Industrial Design course, students are asked to generate some ideas for improving an existing product and to develop the new product concept, define the product and process designs and build a business plan of the overall initiative. Just to give a few examples of the products studied, students' projects have concerned the redesign of a vacuum cleaner, an electronic transformer, etc. The work is conducted in groups of 4 or 5 people, which are formed by the students themselves. The course is organised according to the four parts of the NPD process: concept development, product design, process design, business plan. For each part, some sessions are dedicated to theory, after which a set of tutorial sessions are offered, during which each group works on its own project. In total, the course provides 12 ECTS credits in around 100 hours, 50% of which are based on theory, and the other 50% dedicated to tutoring for the projects. Each teacher is specialised in the specific phase of the NPD process, not only in terms of theoretical knowledge, but also in terms of professional practice. Hence, the improved, re-designed product studied by students develops from the idea to the final industrial version, while respecting the business plan, all throughout the period of the course. All the technical and non-technical hard skills are thus used on a real product. Real problems need to be solved and students themselves have to choose the specific theoretical tools to be implemented. Hence, students can appreciate the skills they are using to successfully manage their project. The involvement of students in all the phases of the NPD process allows them to conduct the phases in parallel whenever possible, in coherence with the concurrent engineering approach. Furthermore, working in a group should favour the development of professional and soft skills, in particular those regarding conflict management, coordination and communication.

2.5. Course design: evaluation process

The evaluation process is divided in two parts: an individual written theory test and the group project evaluation. The individual test includes open theoretical questions concerning all the topics and issues presented during the course. The evaluation of group projects is based upon five elements: four written reports, and a final presentation. The four written reports describe how students have conducted the four phases of their project. An evaluation for each report is provided by the pertinent instructor. The final presentation is discussed with a committee of professionals, who are qualified to evaluate the industrial feasibility and quality of the projects. Involving professionals, who directly participated in innovation processes, is fundamental for ensuring the multidisciplinary skills to successfully participate to the innovation process [23]. Students should convince the committee that the project is actually worthy, feasible, in line with market needs and economically sustainable. Soft and professional skills concerning team working, effective communication, interdisciplinary abilities, and awareness of the external environment [5] are also evaluated during the presentations.

3. RESULTS AND DISCUSSION

3.1. Students' results

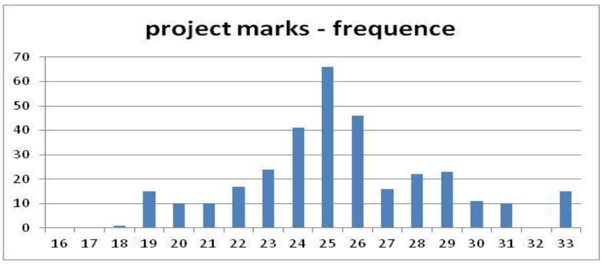
In this section a quantitative synthesis of the results is given. Given the exploratory (and theory building) nature of this study, this is given to provide a comprehensive picture of the students' performance, and it is not aimed at validating the proposed teaching approach. Table 2 gives some descriptive statistics of the results, distinguishing the two parts of the evaluation: the project and the written theory test. The total number of students evaluated is 327. This means that our analysis is based upon 327 individual written tests and 81 group projects, which involved the same 327 students. Comparing grades obtained in groups to the ones obtained individually is interesting for verifying the effect of group working on the final performance of students. As shown, there is not any relevant difference between the two parts of the evaluations, in terms of mean, modal and median values. Standard deviation is limited. As concerns the difference between the two parts of the evaluation, the mean and median values are close to zero, even if the modal value is -2. So the project marks are somehow lower than the written test, and there is a higher standard deviation.

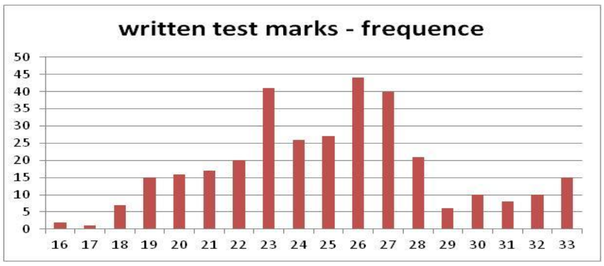
Table 2. Students results (the Italian marks range is 18-30. The maximum evaluation, "30 with merit", is usually translated in numbers as 33)

	Project	**Written test**	**Difference (project – written test)**
n. of students	327	327	
mean value	25,44	25,02	0,42
std. dev	3,28	3,81	4,61
modal value	25	26	-2
median value	25	25	0

Going more in depth in the two parts of the evaluation, figure 2 gives an overview of the distribution of the marks. This brings into evidence that there is some difference: even if the mean values are very similar and the median values are identical, the evaluation of the projects are more close to a very tight, normal distribution, while the evaluation of the written test is more uniformly distributed. In other words, the projects bring the majority of the evaluations towards the mean value.

Figure 2. Distribution of the students marks





The analysis of the correlation between the evaluation of the two parts, (not reported here for sake of brevity) suggests that there is no correlation.

Moving to an in depth analysis of the evaluation of projects, table 3 distinguishes the marks achieved by students in the five parts evaluated. The descriptive statistics reported here is referred to the 81 projects evaluated, each project referring to groups composed typically (with some exceptions) of 4 students.

Table 3. Evaluation of projects

	Concept development	Product design	Process design	Business plan	Project presentation
n. projects evaluated	81	81	81	81	81
Mean value	27,12	25,10	24,48	25,56	26,13
Std dev.	3,83	4,57	3,85	4,05	2,63
modal value	30	26	25	25	28
median value	27	26	25	26	26,75

Mean and especially modal values for those parts of the project that require mainly technical specialised skills (product and process design, business plan) are lower than those requiring the integration of different typologies of technical, non-technical and soft skills. We have also checked for correlations among the various parts of the project evaluations (Pearson), though it is not reported here for the sake of brevity. No statistically significant correlations have been found.

3.2. Discussion of results

The results illustrated above suggest some interesting issues concerning the effectiveness of design based learning when applied to the teaching of innovation to engineers. As described in section 2, innovation is intrinsically a discipline requiring the integration of technical engineering and non-engineering skills, as well as soft skills, such as team working, creativity, and leadership. How the Industrial Design course described in section 2 favours the integration of different typologies of skills is partially indicated by the evaluation of the presentation and concept design parts of the project. Indeed, these two parts are those that require the maximum level of integration of different typologies of skills, both soft/professional and technical. As the evaluation of these two parts presents the highest mean, and especially modal values, we can argue that the integration required has actually been achieved. Evaluation mean and modal values for the other parts of the project, which require more specialisation of technical engineering competences, are lower. This suggests that DBL, conducted by means of team work, is particularly effective precisely when there is the need to make students be able to use their competencies in an integrated manner, applying both technical and professional/soft skills. As concerns the development and application of technical specialised skills, DBL does not seem to be so effective. This is also confirmed by the fact that the results of the individual written test are similar, or even lower, than those of the projects, especially when looking at the results of the three more technical parts. So, DBL with working groups does not seem to add great value when the teaching objective is the specialisation of technical competencies, while it is effective for supporting their integration.

Concerning the development of professional skills, the course on Industrial Design allows for the evaluation of some of them, such as the ability to function on multi-disciplinary teams, the ability to communicate effectively, and the capacity to understand the impact of engineering solutions in a global, economic, environmental, and societal context [5]. This set of skills can be evaluated by the marks achieved by students in their presentations given to the committees, which include external business experts. From this point of view, the results achieved by students are very positive, as the mean and modal values are both very high, especially in comparison with the three more technical parts of the project. Hence, it can be argued that the development of professional (or soft) skills can benefit from DBL with team working.

Some negative effects also emerge from our experience of DBL.

The marks achieved by students in the two parts of their evaluation are not correlated between them. Comparing the marks of the same student in two types of examination, individual and in group, is interesting especially in terms of effectiveness of two types of learning approaches, “passive” or “active”. Obviously, a deeper understanding of this lack of correlation requires investigating the topics of performance of individuals within groups and of teams’ dynamic [20; 21], which are out of the scope of this paper.

Furthermore, the project marks smooth over the evaluation, reducing the differences between good and bad students. This is an effect that can be related to the several difficulties that characterise project-led learning, such as differences in motivation and pace of work among team members, time management, interpersonal problems, and free-riding [20; 16; 21]. Such a smooth over effect, which could be perceived by students [16] may be negative in terms of motivation, and can reduce the willingness of students to actively participate in team working.

4. CONCLUSIONS

This paper deals with the issue of teaching innovation management to engineering, which is recognized as a crucial topics in most important engineering schools [26]. The paper presents the experience of a DBL course on the management of innovation for industrial engineers concerning the NPD process. In particular, two main results of this study are relevant. First, the paper proposes a model for designing courses on innovation and new product development, which could be used in engineering schools. Such a model, presented in figure 2, allows for tailoring the contents of the course in coherence with the specific technological fields of innovation, by changing technical engineering contents while maintaining the technical non-engineering ones. Second, the eight-year experience allows for drawing some tentative conclusions concerning the effectiveness of DBL in the field of the management of innovation. Our results suggest that such a learning approach seems to be effective for developing the ability to integrate technical engineering and non engineering skills and to develop professional “soft” skills. The DBL approach seems to be less effective for supporting the specialisation of technical competences, which are necessary in the field of innovation.

The study presents several limitations, especially concerning team formation. Indeed, we have adopted only self selected teams and thus we are not able to evaluate effects related, for example, to gender, type of background (Bachelor's), and age, which are relevant in team working. Future experiments could be conducted with instructor selected teams, in order to investigate whether and how such factors can influence the effectiveness of the approach. Future research could also be devoted to compare the results achieved in this study with those obtained through other teaching approaches, in order to verify the effectiveness of DBL. Another relevant limitation concerns the theoretical background, which is currently rather focused on problem-based learning, with limited attention to other teaching approaches and, more generally, to educational research. Hence, future effort could be devoted to enrich the theoretical background.

ABSTRACT

The ambition of our engineering school is to train competitive engineers who are able to manage complex projects in fast-changing environments. To this end, we have developed a project based course, controlled by teachers (Steering Committee), where students are confronted with a practical long term assignment which includes unexpected events.

Over the six years of experience gained in running the course, the important question of leadership has emerged, even though it was not an a priori explicit objective of the course. In a large group, if responsibilities can be relatively easily identified and assigned, the group dynamic often relies on the presence of one or several leaders. The Steering Committee puts pressure on the student groups to highlight the capacities of the leader(s) and those around him/her/them. The bounds of the exercise are established by the natural peer-to-peer relationships between fellow students in each year group.

Even if the project does not run well, even if the project leader makes mistakes, leadership skills are understood by the whole group and students still acquire skills. We debrief with the students in order to relativize the success of their production in relation to the organization of the group. Different leadership situations are analysed and discussed in this paper.

Conference Key Areas: Engineering Skills, Ethics in Engineering Education

Keywords: Leadership, project management, return of experience

1 INTRODUCTION

A practical knowledge of project management tools and methods is certainly of great help to properly manage a project. However, being able to motivate teams, to take decisions at critical moments, to resolve disputes, to negotiate with customers and other third parties are some of the numerous skills that will eventually make the difference between managers. These so called “soft skills” are facets of what is called leadership. They are difficult to apprehend in the traditional academic education with respect to the technical “hard skills” that an engineer must display as an accomplished professional. Although these key skills are best addressed in a project context, they still remain difficult to teach as they rely on a complex alchemy between students’ characters and aspirations, working group dynamics and circumstances. In this paper, we propose an analysis of group leadership scenarios that we have experienced over six school years in large project groups where the students have to organize themselves. The diversity of scenarios, the extreme sensitivity of team organization to group composition and dynamics, the influence of a teacher’s behaviour and policy once again testify that managing and leading are not the same thing and that complexity remains undoubtedly the main descriptor of human organizations.

2 LEADERSHIP

Literature on leadership is abundant. Politicians, the military, CEOs are obviously interested in leadership. On a smaller scale, leadership is employed within communities, teams or projects. It is in this context of project management that our training meets this leadership skill.
Historically, our project management-oriented curriculum emphasizes task management, i.e. forecasting, planning, organization, quality, risk, documentation, reporting, etc. without explicitly addressing leadership. We are reluctant to use the term "project leader", and prefer the words "responsible" or "facilitator". It is difficult for students - and for teachers - to break the egalitarian relationship between peer students. However, the role of a leader is important as will be shown by the student feedback from section 4.
Leadership includes several functions. (1) Give direction, vision, meaning to work. (2) Decide, arbitrate, select in accordance with the vision. (3) Motivate, inspire, animate, create and maintain momentum. (4) Ensure group cohesion, avoid or resolve conflicts. Ann Senn summarizes this in [1] as "leadership is about inspiring and enabling others to do something that they otherwise could not or would not do”. To do this, "the greatest measure of leadership is the ability to gain the trust and loyalty of others." C. Richard Panico adds [1].

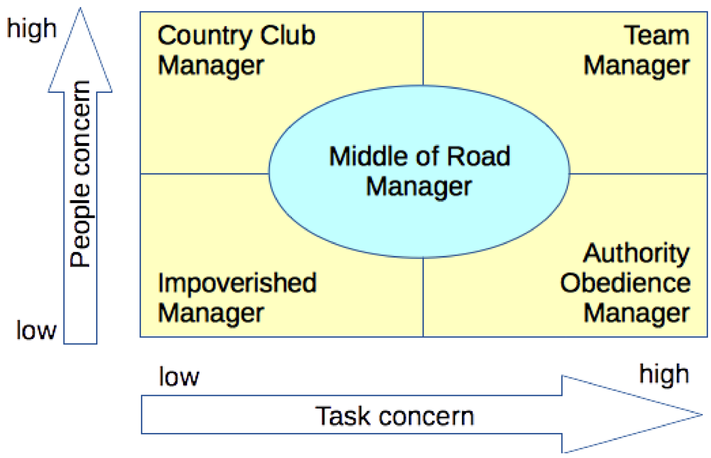

Fig. 1. Blake and Mouton’s managerial grid

In the management model of Blake and Mouton [2], our teaching is therefore mainly focussed on "task" and little focus is placed on "person", thus covering the Authority-Obedience Manager and Team Manager styles (see Figure 1). In practice, the human aspects are obviously very present with a pedagogical backing for the management of confits in particular. The following questions arise: How does the performance of the leaders and especially of the project manager impact the quality of group's execution and the final level of production? Is there a clear correlation between good managers and good results? Can the leadership skills be acquired in educational experimentation? The next section describes our current pedagogical choices.

3 PEDAGOGICAL ORGANIZATION AND EXERCISE LIMITATIONS

3.1 Educational situation for students in the co-op engineering program

In our undergraduate school, we train engineering students, most of whom will be future managers, in a three-year Information and Communications Technology (ICT) program. They have a particularly strong profile in the technical area, which they wish to practice further on at a high level or even at an expertise level. Our training is carried out in a school-company co-operative program with periods of several months at both sites. In the first and second years of school the students, who then work in small groups, discover the traditional tools of project management such as the analysis of the client's needs, planning, risk and delay management. At the end of the second year, the students are thus armed to manage simple, well-targeted projects in small groups. In the third and final year, we bring an extra dimension by putting the students in a position to undertake a complex project in a large group where random situations arise irregularly. Our goal is to bring the students, who are generally much more centred on technical skills, towards strong skills in project management methods [3]. This exercise has been carried out six times and has evolved to a course unit that now lasts 63 hours spread over 12 weeks, consisting of a few lectures and three-hour long tutored sessions.

3.2 The type of technical projects

What could be better than having the students carry out a project [4] in order to make them discover the notions of complexity? The director of the school, together with his executive committee, is the client of the specific projects that we propose to the students. When we initially designed this course unit we proposed a project whose technical core was centred in the ICT area where the students already had acquired some expertise. However, the students' taste for these technologies is such that, contrary to our expectations, the energy spent during the activity was focused on the technical aspects at the expense of the organization and the management of the team. Since this first inconclusive experience, we have chosen a project whose technical framework lies completely outside the skills already acquired by our students. These projects are chosen outside the students' normal comfort zone of technical skills, which ensures that they are equally unprepared for the technical tasks to be accomplished. After the initial moments of destabilization, the groups have to organize themselves to acquire the needed technical skills and to distribute the work to be performed in order to try to reach the client's objectives at the project end. It is at this stage that we see natural leaders emerge and contribute strongly to the structuring of the group. Much of the work at the beginning of the project is then people centred and on the organizing of the group. Conversely, in the absence of a leader, we have observed that this "forming" phase is slow and unproductive [5, 6].

3.3 Course organization

To introduce complexity into this course we have addressed several parameters which, once aggregated, make the project management complicated. First, we divide the students into two groups of about fifteen. This high number of members forces the group to structure itself effectively. We let the groups organize themselves autonomously. It is up to them to choose the project manager. We claim that the choice of leaders by and for the group is a fundamental element in the structuring of the group. They must also define the management rules that seem to be the most appropriate to them. To organize their project, the students must go beyond their regular friendly classmate structure that they have experienced for two years and create a work hierarchy that will apply during the project. The project manager and work package leaders will have to take decisions that hold and handle conflicts with their peers, a task that is far from simple. To help, a communication coach regularly intervenes to help the students deal with human relations, to address conflict management and to advise them on management methods. Students, who wish to do so, can consult this coach freely for counselling.

A Steering Committee (SC), made up of eight professors of different cultures and skills, organizes the course. This SC only intervenes in project management aspects and organization of groups. The SC organizes weekly methodological discussions where representatives of the two groups explain how the group functions, what works well and what doesn’t. The SC questions, suggests and formulates proposals that students are free to implement. In general, the SC is not directive; we leave the initiative to the student managers to lead their groups. In special cases of blocked projects, the SC puts pressure on the group to bring out the capacities of the manager and of his team. It is then observed that managers use different strategies according to their personality and according to their experience. Some project managers voluntarily delegate decision making power to the work package leaders while others decide for the group.

After one third of the duration of the course, we organize an audit to evaluate the processes defined by the group. The audit examines elements such as: the hierarchical organization chart of the group, decision-making processes, document management, risk management, time management, and management of internal and external communication. At the end of this audit, the SC makes a report containing recommendations which highlight the strengths and gives suggestions to improve the weak points of the group’s organization.

The SC organizes a debriefing at the end of the course during which the students express themselves on the functioning of the course. Often, they comment/criticize the grade they have been awarded. The SC emphasizes the acquisition of relational and project management skills by relativizing the importance of the technical production. This is an essential moment to make students aware of the skills they have actually acquired during the project [7]. It then becomes clear to the students that the lack of decision-making or bad decisions made at the wrong time during the project illustrate the need for good leadership. The success of the course in these terms is sometimes difficult for our students to accept or understand.

4 FEEDBACK

We present six stories that have particularly struck us by looking at the role of the nominal leader and then we analyse the results. The natural leader is the one that was identified by the steering committee, because of his/her previous actions in courses or projects. A project is deemed a success when the project satisfies the client's request. Over the 6 years there were no project failures, all missions were completed, but they were carried out with varying degrees of effort where the difficulties related mainly to the methodological and human aspects of project management.

4.1 Six stories

Case 1: The first story concerns a project where the natural leader was chosen. He carried out all the expected functions. He proposed a vision by applying an original management style, based on fair management[1]; he delegated and guided; he ensured the cohesion of the team by generating confidence. The project was a success and the work of the team and its leader was unanimously appreciated.

Case 2: In the second group, several natural leaders could have been chosen, but it was another student who wished to try this role. Uncomfortable at first, she was kindly assisted by others and gained confidence and fulfilled the role effectively throughout the project. She knew how to get support when she needed it and the help she got was fine. The project went well and was a success. At the end of the project, she acknowledged that she had met the challenge and was now able to fulfil this role alone. This is one of the biggest individual progressions we have seen throughout the six years of teaching this course. However, she remained more manager than leader. She has benefited from very favourable conditions. So far, she is the only female team leader.

Case 3: In this third story, two candidates wanted to be the project manager. A close vote chose one, leaving the second frustrated. The second student supported the first throughout the project but without conviction. The leader was not confident about his managing abilities. He was made aware of the difficulties of this project by the older students which disturbed him. The team was poorly organized and the progression difficult. The Steering Committee organized an audit and reported on organizational shortcomings. This audit was badly received but served as a trigger. The group eventually reacted to this by banding together. They became aware of their deficiencies and organized themselves better. This was the first time that a “group operating charter” was established and signed by all members. This event then led to a new start and consolidated the leader. Confidence was restored, team spirit strengthened. Finally, even if the technical project had mitigated results, it was a great success for people relationship and management. It is this group that made the most progress.

Case 4: In the following group the project manager stepped forward essentially because no other candidate volunteered. He did the work but did not facilitate the tasks for the team members. He was quickly seconded by a more experienced student. The transition was smooth and accepted with great relief by the whole group. The very slow start limited the technical success of the project. However, efficient cooperation tools, chosen by the group, compensated for the lack of leadership.

Case 5: In this fifth story, the project manager was a rather good manager and leader. The project was a success. But, an event prior to the project disrupted the evaluation phase. A student wished to “give a lesson” to another by taking advantage of the freedom to individualize the marks, in order to sanction her. He managed to federate a majority of the group around him and organized a meeting “as a court". He took advantages of some late deliverables to justify the penalty. The project leader saw the problem coming, came to seek advice, but could not prevent the split in the group. He reduced the punishment by secretly giving some of his own points to the sanctioned student.

Case 6: In this group the project manager was again the only (reluctant) candidate. He already practiced project management in his company. However, while running this project he did not adapt and sometimes opposed the requests of the Steering Committee because “he did not practice them at work”. He said and showed that his role did not really interest him but nevertheless persevered. The group was much divided. The project manager was isolated and only one out of the other fourteen members willingly accepted to help him in

1 https://fr.wikipedia.org/wiki/Management_équitable, last view 4/2017.

carrying out the tasks that he considered unnecessary. The management part was felt as a constraint. The technical sub-group almost became autonomous by doing the technical tasks and ignoring the management work. Finally, the project was a success from a technical point of view, but the management and the coaching of the group were a failure. The members of the technical sub-group criticised him for obtaining a mediocre score.
We have tried to classify the different cases according to the typology of the leader at the beginning of the project and the degree of success of the project: Table 1.

Table 1. Position of different cases

Choice of the leader / Project result	**Natural leader**	**Accompanied leader**	**Leader by default**
Successful management	Case 1	Case 2	
Hampered by the leader		Case 3	Case 4 Case 6
Hampered by the team	Case 5		

4.2 Analysis

Our first question is about whether such project management experimentation allows students to build on leadership skills. We complete our analysis with a quantitative study based on the students' perception of their skills in a technical approach to project management. We study skills evolution between the beginning and the end of this students' final year project course unit [7]. One question was: at what level do you consider your ability to lead a project?
In Figure 2, we can see the results for 4 student year groups (about 120 students). The graphs show a rise in self-assessed competency in the notion of leadership, with even some of students considering themselves experts in the question.

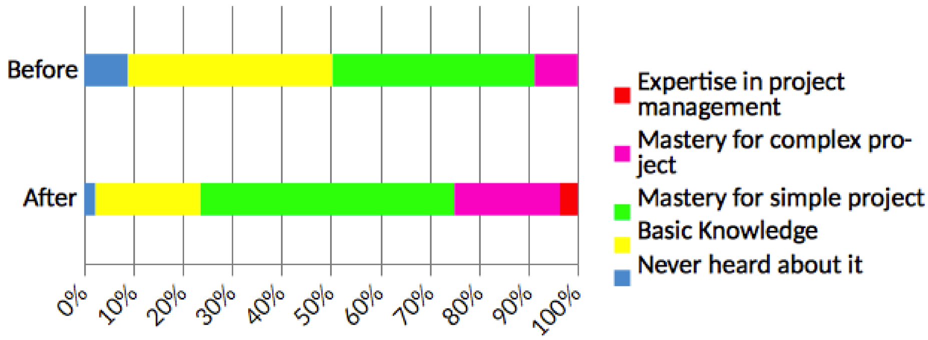

Fig. 2. Ability to hold the position of project manager (all cases 2013-2016)

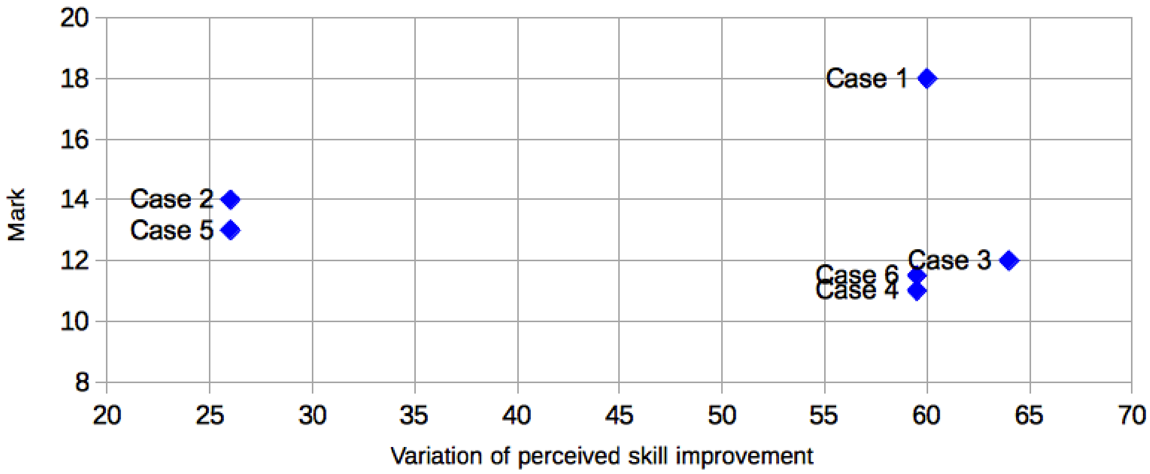
In the appendix, we present these results, year by year, which make it possible to identify the different cases of study. We find that no student in the 2014 year group felt he was an expert in leadership, whereas for other year groups, the two leaders often replied that they had acquired expertise. In case 2, the steering committee considers that the leader took this role in order to test his competency in a learning situation but does not yet consider himself ready to do so in a professional situation. In case 5, the setting up of a court and the displayed support of the project leader to the "accused" person surely created a loss of confidence in his managerial skills.
Our second question considered the link between the group's results and the availability of a good leader. One way to consider the result is to look at the mark obtained during the

course. We do not have an objective criterion for what constitutes a good leader, so we have based our analysis on the evolution perceived by the students of their leadership competency. To do this we create a score that assigns an increasing number of points to the level of competency as perceived by the student. We have taken into account the difference in score before and after the project, case by case. We then evaluate the correlation between this score (which measures perceived improvement in leadership competence) and the final mark (Figure 3).



Case 1: the survey was not created at this time, so it is an approximation of skills variation.

Fig. 3. Comparing marks with perceived competency variation

We find that we cannot correlate the mark with the improvement in leadership competency. To start with, all the cases are different and also the mark considers competencies broader than the simply leadership, even if the starting hypothesis was that a project can't succeed without a good leader.
Other results, more qualitative, emerge from the individual student feedback, observations by the steering committee or debriefing sessions at the end of the course.
We had 6 different cases whereas the pedagogical framework was the same from year to year. Those who were project leaders undeniably learned more than those who were team members. Some project leaders made the effort to give regular feedback of their experience to members (case 3). Only one case had the curiosity to perform a bibliographic search on management methods and to share them with others (case 1).
It is then observed that managers use different strategies according to their personality and according to their experience. A certain project manager voluntarily delegated decision making power to the work package leaders while another decided for the group (Case 6).

We also found that project manager did not necessarily mean leader. Some team members were leaders in their behaviour, in their relationship to others. In such an exercise, it became clear that the peer-to-peer relationship prevented the project manager from implementing of the complete set of managerial incentive tools available in a company, due in particular to the absence of a hierarchical means of pressure.

5 CONCLUSION

The various stories that we, teachers, have observed over six years require several comments. First, taking into account initial parameters such as project group composition and project topic, project developments and group dynamics have continually surprised us. Hence, the Steering Committee has to react wisely and with humility as no predefined scenario was flexible enough to remain unchanged for more than a few weeks. Second, this project experience and the deliberate pressure that the steering committee puts on student groups often lead to the feeling that the project has partially or totally failed, leaving both teachers and students with the bitter feeling that results and achievements were small compared to the efforts made. Hence a debriefing session is mandatory but several weeks after: students realize with hindsight how much they have learned in terms of organization, behaviour, vision, reporting, etc. Third, the leader designation process is somewhat particular (group of classmates, many possible leaders, collective process to make a leader emerge) and does not correspond to what occurs in an industrial context. Leadership is then approached in a different way that is maybe more general, so the outcome is different.

This project course was designed primarily to teach project management methods in a practical way. There was no deep reflection on leadership and relations between leadership and management. After six years, it appears that this kind of project cannot be completed from a pedagogical point of view without a clear vision of what we intend in terms of leadership training. If we all agree on teaching good management methods and techniques, teaching leadership, if possible, poses the fundamental question: do we first train leaders, managers, contributors or all profiles at the same time?

ABSTRACT

We are frequently being informed that Engineering graduates are not ‘work ready’, but lacking in a broad range of generic skills, despite these being mandatory for professional body accreditation. In this case study we present a newly developed second year undergraduate module which explicitly integrates the practice and assessment of generic skills with realistic technical challenges in ‘scenarios’ (week long intensive group projects). It is intended that this format would demonstrate the relevance of the generic skills to the students and hence improve engagement and learning. Observations by staff and feedback from students confirmed the success of this approach.

Conference Key Areas: Engineering skill; Curriculum Development; Attractiveness of Engineering Education

Keywords: Transferable skills; Contextualized learning

INTRODUCTION

There are recurring calls for engineering graduates to be more ‘work ready’ than they currently are. The calls come from industry [1], and are picked up by the media [2]. Engineering has a reputation for being the worst subject area in this respect [3]. Accrediting bodies are well aware of the need for these generic skills, and they are prominent in the UK Quality Assurance Agency’s Subject Benchmark Statement for Engineering [4].

However, as Karatas *et al* found, when students come to university to study “engineering” their understanding of the nature of engineering is often lacking a significant number of the aspects which are described in literature on engineering practice [5]. Thus, as well as learning these generic concepts and ‘soft’ skills, students need to develop an appreciation of their importance. Without this many students will quickly disengage when faced with lectures or coursework on apparently unrelated topics, such as ethics, law and communications skills. This is consistence with research that shows that the subjective value assigned by students to a task or goal has a strong impact on their motivation and hence learning [6].

We ask how we can teach these subjects in a relevant and engaging way, early in an engineering programme.

1 BACKGROUND

A few years back, the Engineering Faculty of our university embarked on an ambitious programme review to tackle this issue [7]. This resulting in a tranche of changes including two new modules to be taken by all first year engineering undergraduates across 9 departments. These modules were intended to introduce generic engineering and work place skills from the first week of the degree programme, and give opportunities to practice them within open ended group projects. We were tasked with developing a follow up second year module, tailored to our specific degree programme (Biomedical Engineering), reinforcing some of the generic skills and introducing more.

A review of these first year modules[2] indicated that students liked the ‘scenarios’ (intensive one week group projects, during which all other teaching stops), however there was too much other assessment in the modules (individual assignments addressing one soft skill at a time, e.g. ethics) and the students did not always understand the relevance of the taught sessions. Staff were also broadly supportive of the scenarios, seeing their benefit in developing the student’s team work and project skills at an early stage but there was some concern that they left less time for teaching technical engineering skills, such as analogue electronics.

2 DESIGN OF THE MODULE

Our response was a module where each of the taught soft skills was explicitly linked with, and assessed within, and only within, one of four scenarios *Fig. 1*. In addition, we worked closely with leaders of modules covering technical engineering knowledge and skills, so that these skills, too, were reinforced and practiced within the scenarios.

[2] Review based on feedback questionnaires by ~700 students, student focus groups and interviews with contributing academics.

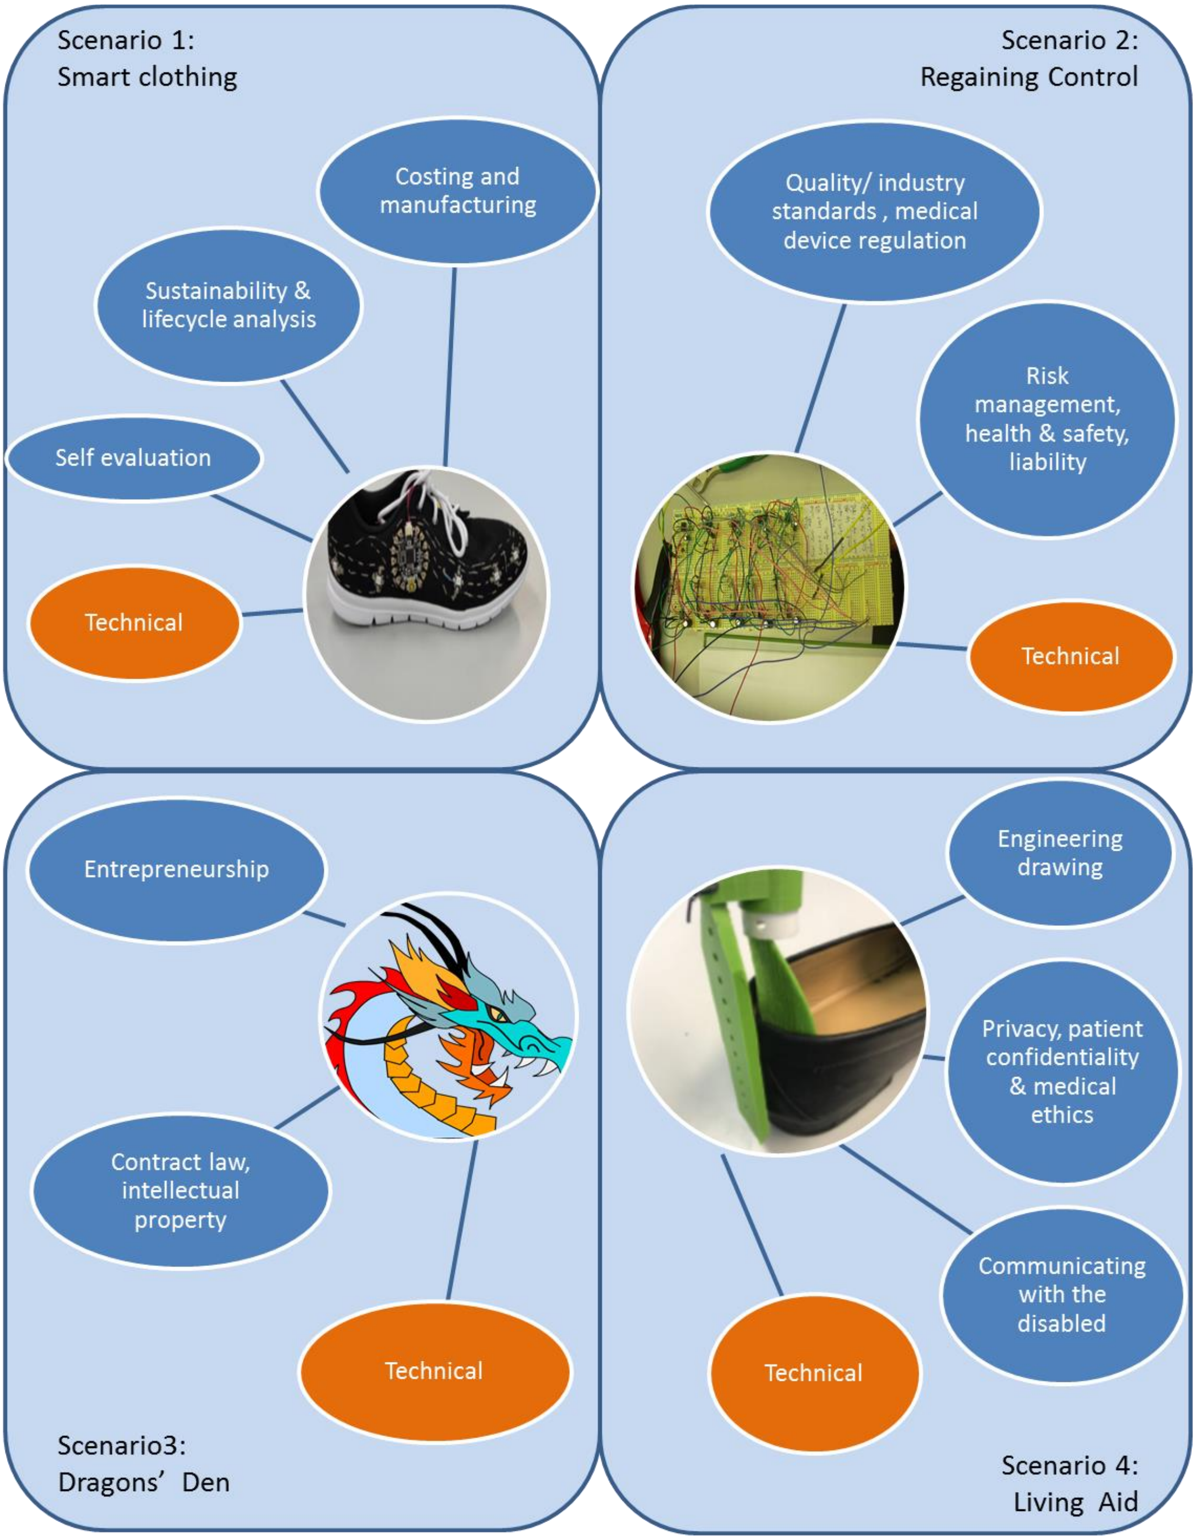

Fig. 1. Schematic diagram of the mapping between professional skills and the four scenarios

Prior to each scenario, students had 3 or 4 2-hour seminars where the linked soft skills were taught. A further way in which we contextualized these generic concepts was the extensive use of relevant case studies and guest lecturers within the seminars, and maintain a focus on why the subject was important to working engineers. For example the CEO of a spinout company taught about costing and manufacturing based around his industrial experiences, and, in another session, a clinical industrial engineer considered medical device regulations and its impact on a product he had developed.

Each scenario was designed with a realistic story line to contextualise the skills and illustrate how these must be used together within the work environment. In fact the final scenario involved students working with the charity REMAP (http://www.remap.org.uk/) to design a product for a disabled client[3], with the assessment covering their interaction with the client and their use of the design cycle, as well as the technical quality of the final prototype device. Concepts of patient confidentiality, privacy and medical ethics were assessed with the aid of an online quiz in the style of role play with students required to state what they would say and or do in response to plausible conversations with the client *Fig. 2*. The students also had to communicate with three different audiences, adjusting their language and style to match:

a) Discuss with a slightly deaf elderly lady of average education – the client - with respect to details of the design specification;

b) Produce a user guide for the device written in ‘easy read’ – a format designed for people with learning disabilities [8];

c) Give detailed instructions for making the product, aimed at an amateur craftsman.

All three represent audiences they are likely to interact with in their working lives, but all are different to the peer-to-peer and peer-to-lecturer communication students are used to.

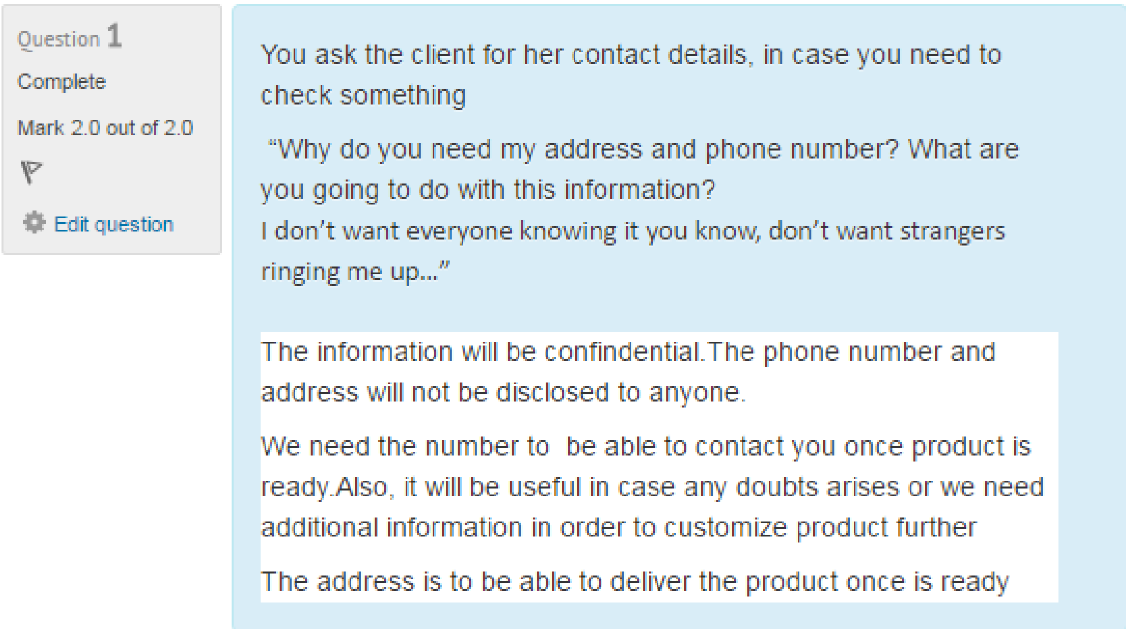

Fig. 2. Example question and student answer from patient confidentiality, privacy and medical ethics quiz.

Each scenario contained individual and group elements of assessment, and one of two mechanisms of moderating group marks to reflect individual contribution:

[3] For the first year the client required a product to enable her to fit and remove her glasses, despite being unable to lift her hands to her face. In the 2nd year the students sought to design a shoe fitting aid for a client whose specific bending and balance constraints made commercial devices inappropriate.

a) Team contribution questionnaire
b) Manual moderation by lead facilitator where there is was demonstrable inhomogeneity in the commitment/performance of the students in the group

3 FEED BACK

We have just completed our second year of running this module with mean overall module grades of 66% for the 1st cohort and 69% for the 2nd. The lowest mark was 55% for the 1st cohort and 60% for the second, despite individual components to each assessment, and individual adjustment of group marks where necessary. Being engineers, we followed the design cycle, seeking feedback from students (10 & 21 in 1st and 2nd cohorts respectively) and staff (4), and improving aspects in light of this. Students completed the department's standard module review questionnaire, and were encouraged to comment informally during personal tutorials and with the module lead during the scenarios. At least one member of staff was present, in the lab were the students were based, for the duration of each scenario, and we would informally brief each other as to the observed group dynamics and productivity. Some of these briefings were by email.

The first year that the module ran, students commented that it was the "first time that ever had to work as a proper team to get something done" and that they had "learnt much more than just electronics and programming skills". However as a teaching team we realised that we needed to be more explicit to the students, with respect to the role of the soft skills in the scenario and related assessment. It was also important to incorporate the soft skills and generic concepts into the story line in a plausible manner, to prevent the associated assessment from feeling like contrived add-ons.

So we made some minor changes to our plans for the next scenarios. These were evidently successful because at end of the third scenario (styled like the TV series 'Dragon's Den'[4]) our judging panel, which included an industry specialist, were impressed with the student's engagement, and one of the research groups we had partnered with asked the students to come back and share their findings.

Unsurprisingly, in the second year the module ran more smoothly, though we will be continually refining it in the years to come. Indicative of its success was the way the students handled the final scenario:

a) They were fully engaged and scored well in those sub-tasks which explicitly tested the generic skills assigned to this scenario.
b) It was observed that they required less intervention by the facilitators, and managed their time and interpersonal relationships markedly better than in their previous scenarios[5] – skills taught in the first year, but which, it was found, they needed further advise on.

Themes in the student feedback, free comments section, included preparation for "real life" ("In general, the module was rather helpful in placing me in real life

---

[4] Students, acted as entrepreneurs, developing and presenting a business plan for the commercialisation of a research output from a UCL research group.

[5] For example. During Scenario 2 facilitators noted, with concern, the disunity and poor group dynamics of one team. Despite intervention, this continued and was also commented on in the report of an independent staff member who assisted with part of the assessment (a mini viva). Individual debriefing/counselling sessions were held with the two students affected and when (the random generator) placed them together for the 4th scenario, they were observed by facilitators to be in a functional working relationship.

situations, allowing me to grow in teamwork.”),enjoyment (“I really enjoyed the scenarios”) and a positive sense of challenge (“The module was quite challenging but we learned a lot and used different skills in each scenario”). The only negative comment was from one student who felt that the group mark did not adequately individual effort. Additionally, in a general feedback session, a second year student responded to a first year’s concerns about the relevance of taught material by describing how they had thought the same at end of their first year, but having subsequently used those skills, they now understand their importance, as well as the relevance of the generic skills taught this year. This further confirms the importance of teaching generic skills in context, and the success of our integrated approach.

4 SUMMARY

Generic skills are an essential part of engineering education, but teaching them in a meaningful way which engages students can be difficult. We have shown that by incorporating them into technical scenarios which give them plausible real-life contexts, students more quickly realise the important of these topics, and hence engage with learning about them.

5 ACKNOWLEDGMENTS

This authors would like to thank Eve Hatten, our competent, creative and inspiring Lab Technician, and rest of teaching team, including guest lecturers, without whom this module could not have run.

ABSTRACT

Industry and academic research labs increasingly use Electronic Laboratory Notebooks (ELN). In engineering education, the ELN affords new laboratory technologies and pedagogies requiring embedding rich data and supporting virtual labs. We present a student-led design of a prototype ELN based on Microsoft OneNote software for our undergraduate engineering programmes. The solution addresses the requirements for lab redesign aspirations around new laboratory pedagogies requiring entirely digital workflows. To enhance the solution's ecological validity, students themselves developed it while undertaking their existing undergraduate labs. The result is an ELN based on the digital notetaking software Microsoft OneNote. We make available a requirements and design tool that includes a set of 21 use cases, 102 requirements, and 32 failure modes. Staff and student feedback is reported. The work will assist engineering and science faculty looking to introduce an ELN solution into their curricula.

Conference Key Areas: Open and Online Engineering Education, Curriculum Development, Skills and Engineering Education.

Keywords: Electronic Laboratory Notebook, Microsoft OneNote, Educational Technologies, User acceptance.

INTRODUCTION

Digital notetaking is becoming the norm in personal and professional endeavours due to the maturity and ubiquity of software and hardware devices which provide capabilities beyond paper. In the laboratory or workshop in undergraduate engineering education, paper notetaking and capture is common and often preferred; sketching is perceived as easier on paper [1], there are several competing technology options for digital notebooks with no obvious winner [2], and faculty staff can be late and/or cautious adopters of new technology [3].

The Electronic Laboratory Notebook is commonly used in industrial research laboratories where there is a strong requirement for capturing Intellectual Property (IP) [4]. ELN use is less common in engineering education; the IP requirement manifests itself chiefly for assisting assessment logistics and plagiarism detection, the latter which is primarily deterred by designing it out of assessment [5]; retaining paper notes may in fact reduce student motivation to plagiarise through increased effort compared to “copy and paste”.

Several recent studies have evaluated the perceived benefits of ELN using contemporary hardware devices such as laptops and tablet devices with stylus. A non-exhaustive list of ELN benefits from these studies includes graph plotting; rich media use; connecting to equipment for control and data capture; embedding and analysing raw data; automatically saving progress; revision capabilities, standardisation and neatness via templates, multiple device access; collaboration and sharing content remotely. For staff, ELN benefits include remote assessment; annotation capabilities; auto grading potential; aggregation and searching of students’ work [6] [7].

In this study, we are interested in what student-driven recommendations could be made to engineering faculty for adopting an ELN solution. To answer this, undergraduate students with at least 2 years’ higher education from faculties of biosciences, civil, mechanical, computer, electrical and chemical engineering were tasked to develop an ELN solution based on their experiences. In addition to prioritising feature expectations and evaluating user acceptance, we asked them to consider broader lifecycle issues including training, operations and maintenance. The work was undertaken in the context of developing a contemporary learning space – the Collaborative Teaching Laboratory at the University of Birmingham [8]. We describe the resulting prototype ELN based on Microsoft OneNote software from design and requirements perspectives. We report feedback received from several evaluations, and we conclude with lessons learned and a requirements tool for faculty looking to develop their own ELN.

1 REVIEW OF ELECTRONIC LAB NOTEBOOKS

ELNs have existed since desktop computers first appeared in research labs. The 1980s locally networked computers lead to a focus on developing collaboration possibilities around shared file stores. The hardware and software advances of the 1990’s stimulated increased focus on function and usability such as inputting, capturing and analysing data. The advent of the internet afforded information mining and meta-data to maximise IP value [9].

Their use in Engineering undergraduate education has a smaller pedigree. Several recent case studies have been reported that give a mixed picture in terms of the benefits of an ELN over paper. Notably in [1], students did not generally make use of rich media such as images and video to enhance reporting. In [6], staff and student ratings of a commerical ELN “Lab Archives” were positive in terms of its function, however training requirements were highlighted as a key barrier to uptake. Many ELN benefits come only after the initial note input, such as searching and revising past entries, which may not always be required. The structure to input that the ELN can impose could also be at the expense of the flexibility that a blank sheet of paper affords [10]; structured templates in ELN, e.g. defined sections and autofilling tables with correct formulae, can prevent students from “being able to produce their own structure and engage in organise their work” [2]. These previous works motivated us to develop the requirements and design tool reported here to evaluate potential ELN solutions.

There are numerous commercial ELN softwares used in research activity across sciences and engineering. These include SciNote, LabFolder, LabArchives, LabWare, Docollab and LabGuru. In contrast to these softwares, general digitial notetaking solutions such as Microsoft OneNote and Evernote can be adapted to serve as an ELN, particularly when teaching activity takes precedent over project-oriented research activity. These general softwares benefit from no imposed lab structure, cross-platform support, and mass-market maturity; e.g. in [11], OneNote – the software used in this study – enabled an ELN to be accessible on a newly released smart watch to free up users hands during practical.

The ELN is a part of the bigger challenge to evolve engineering educcation laboratory pedagogy in the digital age. In [12], the proposed Electronic Lab Assessments with Tutoring Enhanced Delivery (ELATED) laboratory pedagogy is typical of modern lab redesign efforts, highlighting the requirement for lab assessment combined with reflective portfolios, demonstrations and reports. All of these outputs contribute to an entirely digital lab profle for every student.

2 REQUIREMENTS AND DESIGN

2.1 Lifecycle and project scope

The ELN solution (*Fig. 1*) was developed by undergraduate student interns over summer 2016. The project consisted of students developing a solution based on Microsoft OneNote for use on tablet devices (Microsoft Surface Pro 4s and Ipad Air 2) and mobile phones and desktop computers while they undertook existing labs from several STEM disciplines. Use cases and detailed requirements were captured. Evaluation activities included failure modes analysis, and user acceptance trials. Students were tasked to consider operational aspects of the solution. These included fault handling and maintenance procedures, and student/staff training requirements including user manuals and training videos.

2.2 Requirements and Use Case

Initial observations and run-throughs of labs resulted in the identification of 21 key use cases with the associated actors, goals, pre-conditions, success scenarios, extensions and post conditions. The use cases are: adding students to notebooks, creating ELN, printing ELN, marking ELN, erasing input, using templates, excusing attendance, creating search queries, viewing content libraries, graphing, adding feedback, viewing feedback, login, logout, adding assignment, view individual student ELN, collaborate, seek assistance, change page layout and view revision history. From these use cases, 102 requirements are identified which are grouped into several sections: User interfaces, functional, performance, hardware, security, software quality. Furthermore, 37 failure modes are identified for consideration during design testing. These are available in the requirements and design tool described in section 4.

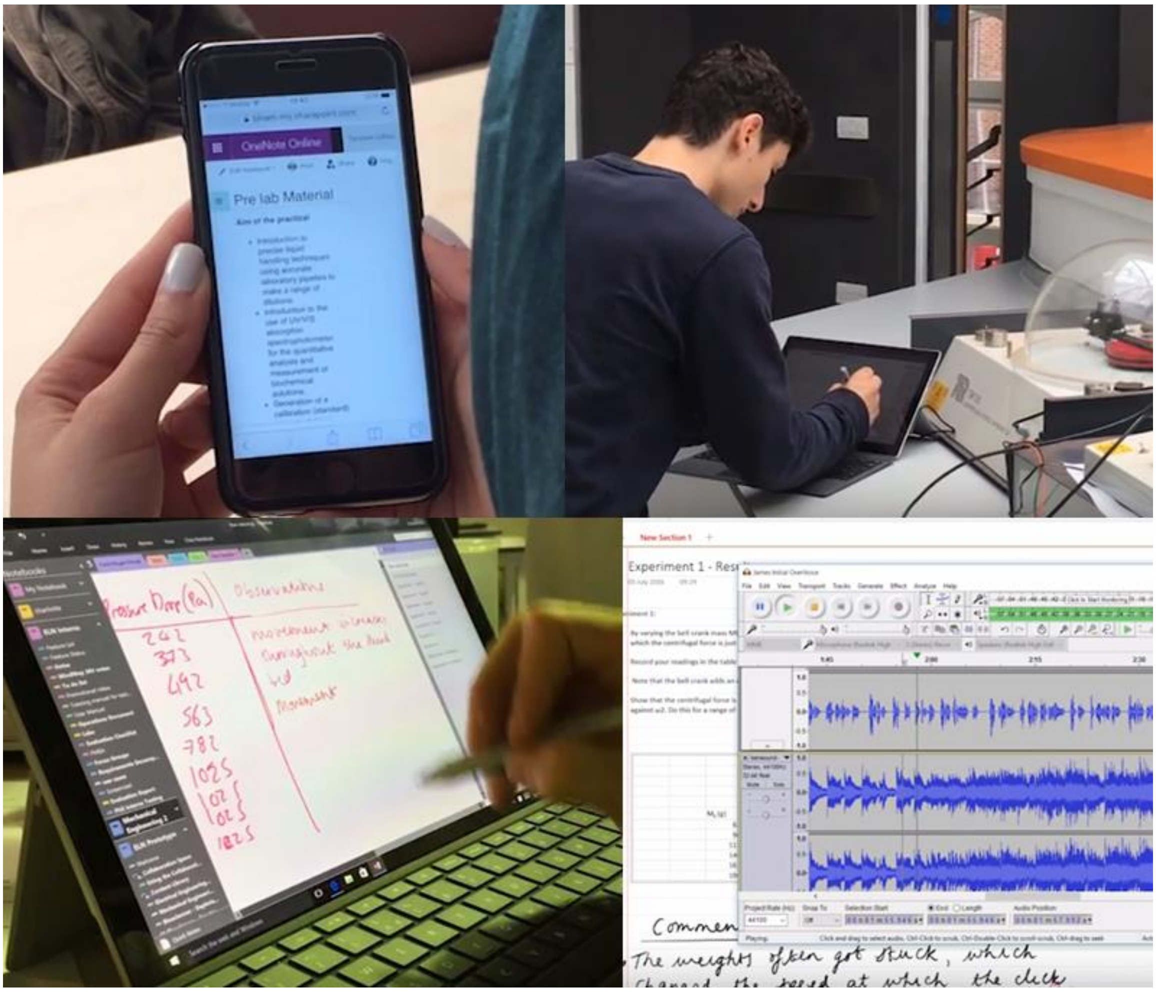

Fig. 1. ELN Solution – smartphone access to pre-lab materials (1a top left), data logging capabilities (1b top right), sylus input (1c bottom left), data embedding (1d bottom right)

2.3 Design

Fig. 2 outlines the ELN solution architecture, illustrating how users interact with the three primary components – notetaking software, cloud service and the Virtual Learning Environment (VLE). The first component is the notetaking software - Microsoft OneNote 2016 with class notebook add-in. It conforms to a traditional notebook with sections comprising of ordered pages. It supports stylus and keyboard input, and the embedding of other objects in-line with text such as rich media, data attachments and spreadsheets. The second component is the cloud service - Microsoft Class Notebook / OneDrive cloud. Rather than students downloading personal copies of the notebook, they all work on this same cloud-based notebook. Student's individual sections are not visible to one-another, and the cloud solution enhances data security and eases assessment logistics; making updating and distributing content efficiently. Important functionality is provided by the Class Notebook plugin. It gives students access to a shared content library and collaborative sections, along with their own individual working spaces which the teacher can access and grade. The third component is the VLE – in our case, Canvas by Instructure. Faculty teaching staff have the choice of marking the notebook through the VLE, or through Class Notebook plugin in line with local policy.

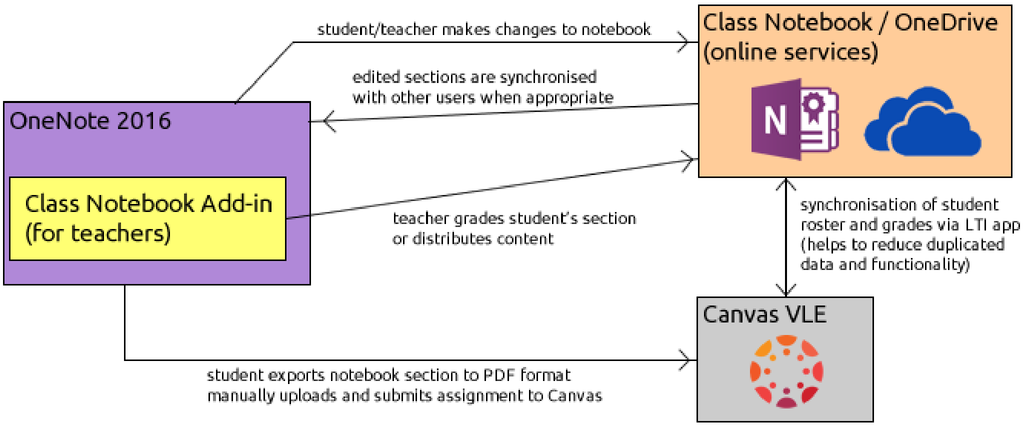

Fig. 2. The ELN architecture based on Microsoft OneNote**.**

3 EVALUATION

3.1 Outcomes from observational analysis

The student developers conducted several laboratory sessions in diverse subjects including chemical engineering, mechanical engineering, electrical engineering, biosciences and chemistry. They made detailed observations during the sessions to ascertain the benefits of the ELN over existing laboratories. A representative sample of the key benefits they observed are summarised in *Table 1*.

Table 1. Key benefits of ELN identified by developer from prototype lab sessions

Existing paper-based Laboratory - observation	**Enhancements provided by the ELN**
Demand by students on staff for orientation and support e.g. locating materials.	*Prelab material in the ELN assists in orientation e.g. VR walkthroughs. The ELN should not to reduce interaction opportunities but instead orient them towards intended learning outcomes.*
Many exercises require students to submit diagrams.	*The stylus functionality appears neater than paper for free-hand drawing but more cumbersome.*
Evidence of lab progress relies on the quality of final answers.	*Students can demonstrate progress by inserting media into the ELN but few do unprompted.*
Lab sheets have a linear structure – students step through them methodically during labs.	*The ELN include pre- and post-lab activity work and also allows students to hyperlink to different sections allowing a non-linear workflow.*
Tables typically require hand written input and the use of calculators to compute values.	*Data is input directly into spreadsheets and tables, allowing for automatic calculation of derived quantities and graphing.*
Students bring a USB stick to the lab to save the data recordings.	*Data logging software can sit on the same platform as the ELN*

3.2 User Acceptance

We conducted several user acceptance studies. 30 undergraduate engineering students were given a demonstration of the solution outside of the laboratory. They were asked to rate it overall on a five-point Likert scale. The average rating was *4.8* with a standard deviation of *0.4*. All but 2 students from this cohort said that they would recommend the solution. 9 academics who teach undergraduate modules were individually presented with the ELN software solution at the laboratory bench. They were asked to run through a mechanical engineering experiment on centrifugal forces shown in Fig. 1b. They each scored the ELN on a five-point Likert scale in comparison to paper notebooks against 14 key features adapted from existing evaluations in the literature [1]. Correspondingly, 19 3rd year undergraduate engineering students undertaking a third-year laboratory in Virtual Reality were asked to use the same ELN software and complete the same questionnaire. Overall students rated the solution higher than the academics (*Fig. 3*). Both student and academics rated most functions higher than paper, assumed to be a mean score above 2.5. The weakest comparisons with paper were “1. making handwritten notes”, “2. adding formulae”, and “3. sketching diagrams”. This is despite the use of tablet devices equipped with a stylus, and it suggests that core notebook functions of data entry are still preferable in paper despite recent hardware advances. There is a smaller variance in the student scores compared to academics which may be attributed to the greater number of participants.

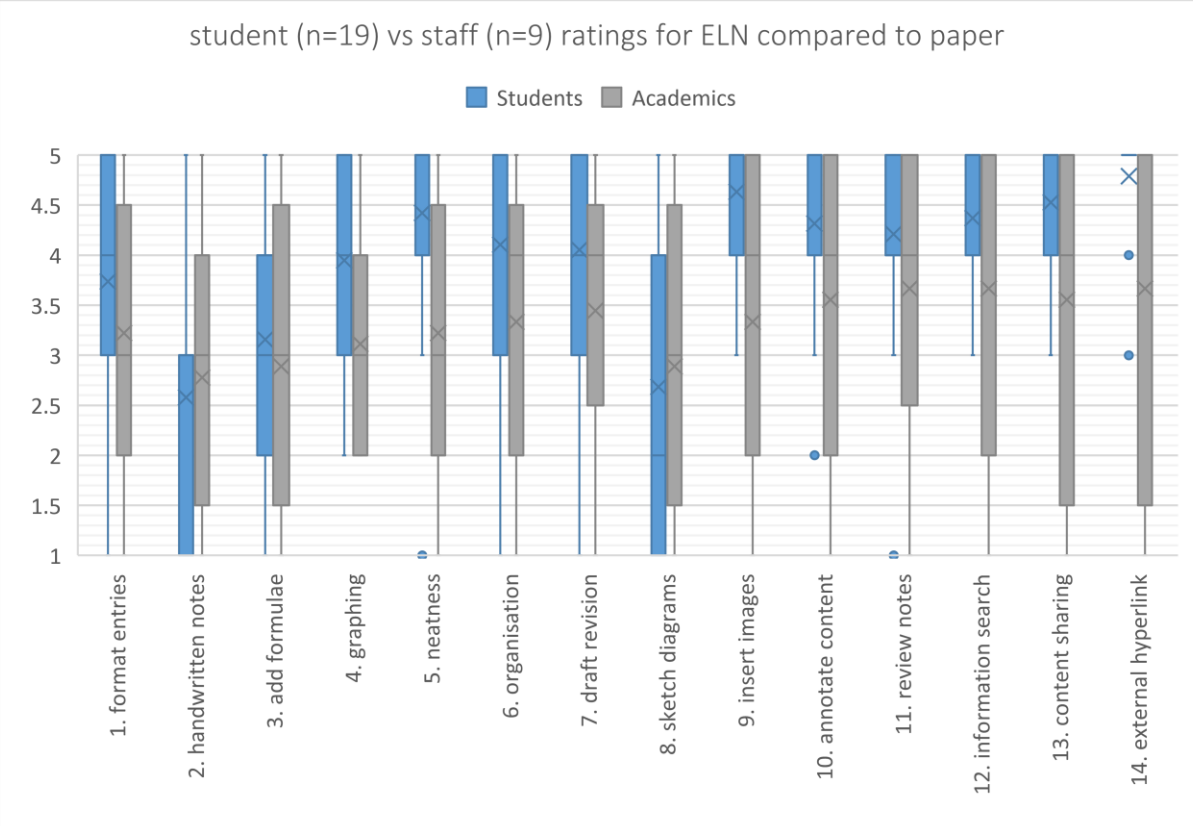

Fig. 3. Student and Academic ratings of ELN Feature benefits over paper based laboratory.

Academics were further queried on assessment of notebook, and all respondents considered grading the work via the VLE more important than grading the work within the ELN solution to ensure common practice with other non-laboratory assessments. Positive comments from academics included “Set out of information is good, input of data occasionally fiddly”; “It prepares students for the next academic and professional levels”; “Minimises paper use, allows rich content, interaction and data sharing.”; “Makes it easier to prepare the lab work and facilitates group working.”; “Easy to mark”;

"easy to keep protocols/instructions updates". Negative comments from academics included "The benefit should be on the lab itself and its redesign to take advantage of the ELN.". Positive comments from students includes "Easier to organise, share and implement pictures, videos and record audio" and "It is neater. Straight lines are easier to draw, easier to copy image". Negative comments from students included "Computer could crash midway through notetaking". Finally, 6 students undertaken a mechanical engineering laboratory in fluid dynamics were given the ELN to make notes instead of a paper, which was used by the other 12 students in the cohort. The key difference between the groups was that a key component of the experiment – graphing pipe pressures and flows – was automated by spreadsheet. This reduced the time taken by students to produce results and lead to more time available for results analysis.

4 ELN DESIGN AND EVALUATION TOOL

We have made a tool to assist engineering faculty in evaluating their own ELN solutions. It consists of a set of 21 use cases for ELN, 102 associated requirements, 32 failure modes for designing against, and the architecture and user manual for our OneNote based solution. It is available on request to faculty from the following URL: http://www.tinyurl.com/SEFI-ELN-REQUEST. A student-produced video of the solution is also available at this URL.

5 SUMMARY

An ELN for Engineering faculty is presented and evaluated. It encourages rich media use and makes data processing and manipulation efficient through e.g. embedded spreadsheets. Collaboration capabilities are a key strength which allow sharing of data and notes. Software for many types of lab equipment can be installed on the hardware platform which runs the notetaking software to facilitate data embedding. The ELN simplifies the submission of lab work and eases marking burdens. Against this, like all cloud-dependent solutions, collaboration functions require stable network connections, and there is an outlay required in terms of equipment, maintenance and training. Despite these shortfalls, it reduces the quantity of paper required reducing carbon footprints, and promotes digital literacy.

With the current advances in mass-market tablet devices with stylus and cloud-based mass-market notetaking software that operates on multiple hardware platforms, ubiquitous ELN in undergraduate engineering education is now realisable. Future work includes enhancing the laboratory sessions that currently use the ELN to take advantage of the graphing, data embedding and collaborative features that the technology affords.

6 ACKNOWLEDGMENTS

The authors would like to thank students Moushami Verma, Joseph Crolla, Jonathan Keslake, Tanzeel Gillani, Charlotte Birch, Jeremy Clarke and Project Manager Chloe Hancox for their contributions to this work which was undertaken with an Educational Enhancement Fund from the Centre of Learning and Academic Development at the University of Birmingham.

ABSTRACT

The purpose of this study was the investigation of peculiarities related to the education of managerial competence and to the need of economics and business knowledge for engineering studies students. According to business representatives, many engineering graduates lack of managerial competence and knowledge of economics. The study was performed at Kaunas University of Technology (KTU). A complex investigation consisting of three parts, i.e., an evaluation of students' attitude, an academics' approach analysis and an estimation of the attitude of business representatives as potential employers for high school graduates, has been chosen. The need for economics and business courses for students studying in technological faculties, the features of psychological environment of economics and business studies in those faculties, as well as weaknesses and strengths of learning economics and business subjects were revealed during the research.

Conference Key Areas: University – Business cooperation, Curriculum Development Engineering Education Research, Engineering Skills.

Keywords: managerial competence, economics knowledge, psychological environment, engineering education.

INTRODUCTION

There have been widely discussed about a changeable nature of the studies in higher educational institution under the circumstances of information technologies development and economic globalisation in recent years. The study programs are responsively associated with the changes in labour market, so that the majority of business schools, universities and colleges declare significant differences in the study process. One of the most prime accents is the development of competency education [1], [2]. Competence is an expression of human qualification or ability to act conditioned by the individual's knowledge, skills, attitudes, personality features and values [3], [4]. A public talk with employers indicates that many engineering graduates lack of managerial competence and knowledge of economics. There are very few researches on this subject in Lithuania [5], [6]. Therefore, it is particularly important to find out the competency education problems that Lithuanian higher education institutions faces within the framework of engineering studies realization and with a special focus on the physical and psychological learning environment.
The present study aims to investigate the peculiarities of economics and business studies in technological faculties.
The objectives of the research**:**

1. To explore the need of economics and business subjects to engineering studies students.
2. To disclose the features of physical and psychological environment of economics and business modules studies in technological faculties.
3. To reveal the ways to improve the cooperation between students, academics and employers**.**

1. RESEARCH METHODS

The research was accomplished at Kaunas University of Technology in Lithuania. The data were collected with survey questionnaires in 2016. The method of the research includes a complex analysis: 1) the students' attitude to the need of business and economics studies, to learning and psychological environment in technological faculties and to the cooperation between students, academics and employers, 2) the academics' attitude to the need of economics and business knowledge for students studying in technological faculties, to learning and psychological environment in technological faculties and to the cooperation between students, academics and employers, 3) the attitude of business representatives to the need of business and economics studies for students of technological faculties, to the readiness of young professionals to the labour market and to the cooperation between students, academics and employers. The self-administered questionnaires were consisted of statements and questions. Respondents were asked to indicate levels of agreement with statements using a 5-point Likert scale, which provided following response options: "1 = Disagree", "2 = More disagree than agree", "3 = Neither agree nor disagree", "4 = More agree than disagree", "5 = Agree". Questions based on Likert scale allow to get more useful for the research information and to reduce the amount of questions.

Paniott's formula (1) has been used to calculate sample size (number of respondents), i.e., to ensure reliability of research of 95%:

$$n = 1/ (\Delta 2 + 1/N), \quad (1)$$

Where:

n – Sample size;

Δ – Allowed calculation error;

N – Size of population.

Statistical analysis of research results was conducted by employing the software of statistical data processing, *SPSS* (v23.0) and *Microsoft Excel* (2010).

2. RESEARCH RESULTS AND DISCUSSION

2.1. Students' approach

Purposeful sampling has been used for the formation of an investigative group. Individuals that are most representative in regard of an investigative feature were selected to the formative group. There were involved students studying Engineering Economics (economics subject) and Fundamental of Corporate Management (management subject) in the technological faculties of KTU. The subject of Engineering Economics was chosen by 122 students in the spring semester. The subject of Fundamental of Corporate Management was chosen by 150 students in the spring semester. 170 students, studying in the Faculty of Chemical Technology and in the Faculty of Mechanical Engineering and Design, participated in the investigation (170 questionnaires were handed out). The survey questionnaire was divided into three parts. First part was designed for the evaluation of the need for economics and business studies in technological faculties. Second part was made for the evaluation of learning and psychological environment of economics and business studies. Third part was designed for the study of students and employers relations.

2.1.1. Evaluation of the need for economics and business studies

For the evaluation of the need for economics and business studies in technological faculties, the students were asked whether they would like to study more economics and business subjects. The distribution of responses is shown in Figure 1.

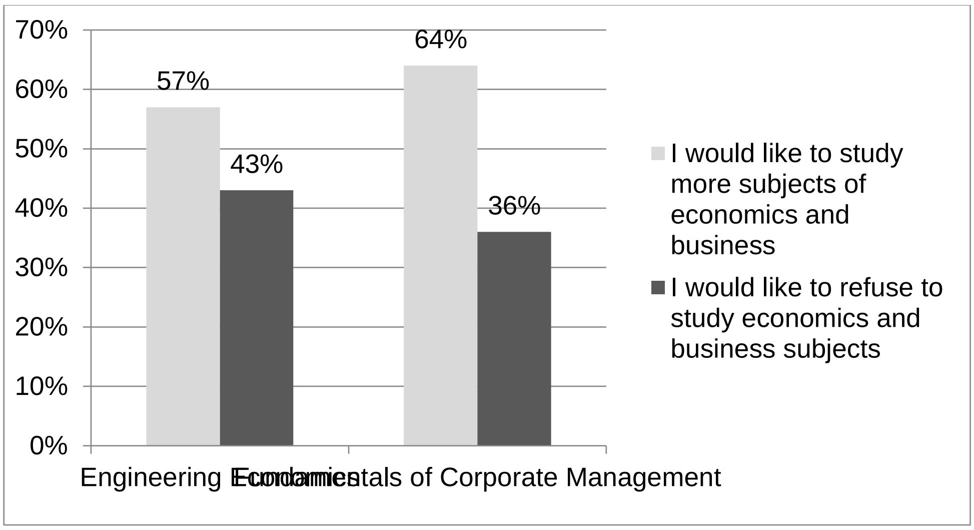

Fig. 1. The need for economics and business subjects, in percent

A large proportion of students would like to study more economics and business subjects. They took the view that it is necessary for their future career and for the integration into the labour market. It is important to evaluate the expectations of students by offering economics and business subjects. The next question was designed to find out whether students have gained the additional competences in studying economics and business subjects. In students' opinion, the studies of economics and business subjects provided the additional competences like a perception of economic terms, common knowledge about an economy and market, and the ability to prepare a business plan. 54% of the respondents believed that it will be easier to take decisions after the studies of economics and business. 61% of the respondents stated that they gained knowledge that would let them to deal with economic and business problems. 52% of the respondents maintained that they have learned to prepare a business plan. 57% of the respondents gained knowledge that will be possible to apply in their specialities.

2.1.2. Evaluation of learning and psychological environment of economics and business studies

For the evaluation of learning and psychological environment of economic and business studies the statements describing these environments were submitted to students. The statements have been made with reference to other authors' [7], [8] researches about the educational environment and its impact on study results. The results of this research indicated that the engineering studies students rated the learning and psychological environment of economic and business studies quite positively. The students took the view that they are physically and psychologically safe during time of lectures. Students have been communicated with academics by email, during outing-lectures to companies, at the time of Medium or KTU events and during time–out between lectures. Most of the students would like to make more contact with academics in the informal environment, i.e., to drink coffee and to discuss on economic and business issues. Students would like more sports holidays, cycling races, orienteering contest and etc.

2.1.3. Students' attitude towards the communication with employers

The purpose of the study of relationship between students and employers was to find out whether the communication with business representatives is relevant for students and what forms of communication are most acceptable for them. The results showed that there are necessary students' meetings with business representatives during the study process. 66.5% of the respondents stated that the communication with business representatives has allowed a better understanding of the practical things. 47.1% of the respondents had it that such meetings have revealed new business opportunities and new market trends. 58.2% of the respondents maintained that such meetings have allowed for better understanding of employer needs and requirements for employees. 58.2% of the interviewees communicated with business respondents during lectures, 62% – at the time of the excursions to company, 14.7% – at the time of business plan contest. The students suggested the following possible communication with business forms as joint projects, product development (business representatives' participation in the process of study), students' projects mentoring, excursions to companies, practical lectures of business representatives, practice.

2.2. Academics approach

10 academics from Kaunas University of Technology participated in the survey. The academics, who were involved in the research, teach Chemistry, Design, Mechanics, Mathematics, Informatics, Electrical and Electronics, Energy and Construction.

2.2.1. Evaluation of the need of economics and business knowledge for engineering students

First and foremost, the aim of the survey was to find out academics' attitude to the teaching of economics and business disciplines in technological faculties. The opinion of academics participated in the study on this point is represented in Figure 2. There are shown the averages of the statements scored up accordance with a 5-point Likert scale. The academics, participated in the survey, had quite a solid positive opinion (average of scores was 4.6) on the need of economics and business knowledge to students studying in technological faculties.

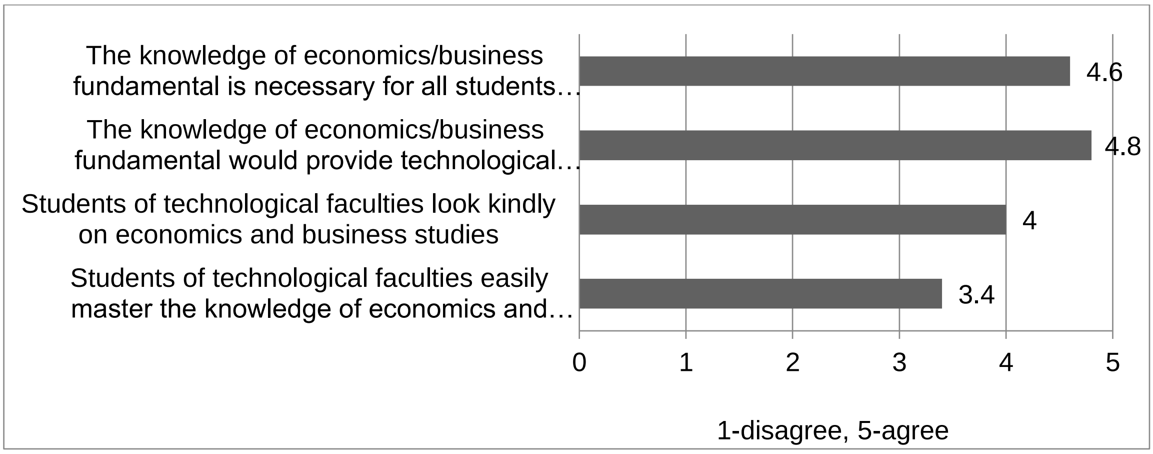

Fig 2. Academics' approach to the need of economics and business knowledge to students studying in technological faculties, in scores

Most of survey participants (average of scores was 4.8) agreed that economics and business studies would provide students with additional competences such as team work skills, the ability to analyze the market situation, the fundamental of corporate financial management, the understanding how to develop a business project, the basic knowledge of business creation, establishment and etc. In opinion of academics, the students of technological faculties look kindly to the studies of economics and business (average of scores was 4), but moderately (average of scores was 3.4) master the knowledge of economics and business.

2.2.2. Evaluation of learning and psychological environment in technological faculties

The next part of survey was aimed for the evaluation learning and psychological environment in technological faculties in terms of teaching economics and business subjects. A proper communication between students and academics plays a significant role in the creating of good social–psychological climate in higher educational institution. However, academics did not have one opinion (average of scores was 2.9) whether students of technological faculties and lecturers teaching economics and business modules communicate after school time. It could be seen from the survey results that academics could not give unequivocal expression whether the informal communication between lecturer and student influences to better results of study subject (average of scores was 3.6). The respondents noted that informal communication between students and academics is available and can take a variety of mutually acceptable ways such as joint visits to companies, business plan contest, joint sports competition and etc. Talking of the adaptation of learning environment for the economics and business studies in technological faculties, the academics quite unanimously (average of scores was 4.1) stated on its relevance and applicability for these studies.

2.2.3. Academics' attitude towards the cooperation between students and employers

The further part of survey was aimed for the evaluation of the opinion of academics lecturing economics and business modules in technological faculties about cooperation with the business representatives at study time. The survey showed that there was given the opportunity to meet with business representatives at the time of economics or business lectures for the most of technological faculties' students (average of scores was 4.3). 90% of academics participated in the survey agreed that such cooperation between students and business representatives is useful. The academics noted the following possible cooperation forms as lectures of business representatives, excursions to companies, career days, business contest, joint events of students and business community and etc. The academics quite unanimously shared the opinion that it is required closer cooperation with the business community not only for students but also for lecturers. It is useful for preparing young professionals who will be in character with the ever–evolving requirements of the labour market. However, it should be noted that not all academics, teaching economics and business subjects in technological faculties, constantly communicate with business representatives (average of scores was 3.8). The academics pointed out the following cooperation ways as lecturer traineeships in companies, roundtable discussions, joint projects, cooperation in the formulation of the topics for course and final works, the solution of real business problems with the participation of students, academics and business community, and etc.

2.3. Business representatives' approach

The purpose of business expert survey was to evaluate the approach of business representatives to the need of business and economics studies for the students of technological faculties, to identify the psychological readiness of students to meet the challenges of the labour market and to find out the ways for the intensification of students and teaching staff cooperation with the business community. 8 experts participated in the research from different companies who hire engineers.

2.3.1. Evaluation of the need of economics and business knowledge for students studying in technological faculties

First and foremost, the aim of the survey was to find out the attitude of business experts to the need of economics and business knowledge for engineering students. The expert opinion on this subject is shown in Figure 3.

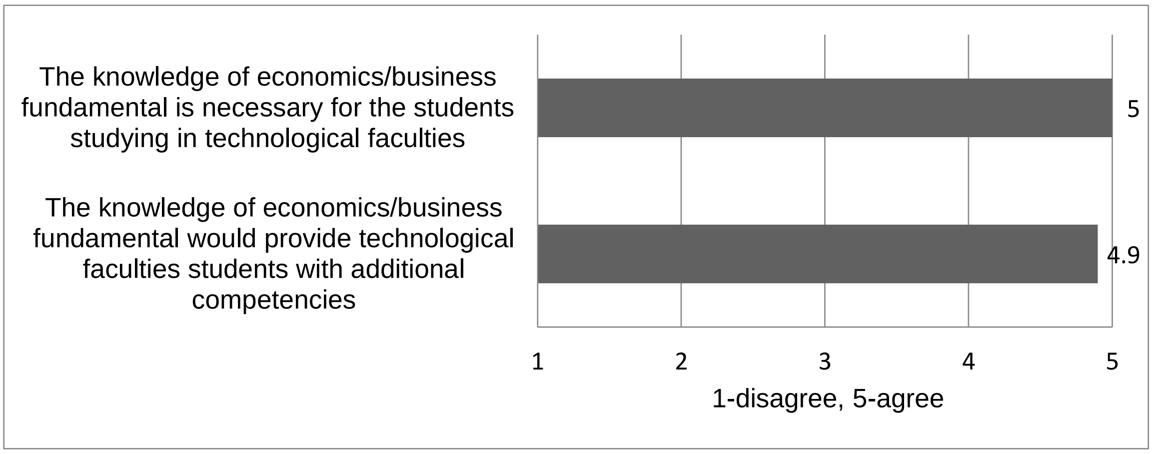

Fig 3. Business representatives' approach to the need of economics and business subjects for engineering students, in scores

The business representatives quite unanimously (average of scores was 4.9) agreed that the knowledge of economics and business fundamental is necessary for the students studying in technological faculties. 100% of business representatives agreed that such knowledge would provide the students with additional competencies. Experts pointed out that the teaching of business and economics subjects enables students to acquire knowledge, which are necessary for the development and marketing of products. In the opinion of the business representatives, such professionals could have a higher chance to take key positions where needed not only professional but also managerial skills. Even if a technical creative work is more acceptable for professional, the understanding how money appear in the company's account and the knowledge of basic economic calculations increase their competencies. The experts pointed out that such staff more objectively looks at their functions and at business, faster and deeper understands the market processes, and the management of business processes. Also they are able to hold forth ideas. That helps them to climb up the career ladder.

2.3.2. Evaluation of the readiness of young professionals to the labour market

The next part of survey was aimed for the evaluation of the opinion of business representatives about the readiness of young professionals to the labour market. According to the business experts, most of the technological studies graduates have the sufficient proficiency knowledge (average of scores was 3.8), which they are able to apply in practice. But more often employers desiderate other competencies of young professionals. Mostly employers desiderate communication skills, good usage of Lithuanian language and courage in making independent decisions. An insufficient knowledge of business and economics, which is an integral part of any business, was mentioned between wants. The business representatives rated ambiguously (average of scores was 3.1) the statement that high school graduates are psychologically ready to take various challenges at work. The analysis of the employers' approach revealed that the young specialist's work opportunities are usually limited by the lack of practical skills and personal characteristics. The majority of young people do not have personal purposes related to the professional activity and are minded to change workplaces. The issues of young professionals' motivation and education of personal motivation, i.e., self–control and pursuit of the objects, remain relevant for employers.

2.3.3. Business representatives' attitude towards the cooperation between students and employers

The further part of survey was aimed for the evaluation of the respondents' approach to the need of cooperation with students and lecturers. The business experts agreed that the cooperation between students and business representatives is essential on purpose to improve the readiness of future employees. The forms of cooperation may be various as lectures of business representatives, student visits to companies, business contest, practice in the company, career days, analysis of case studies, creative workshops, Brain Fights and etc. It is very important cooperation of business community not only with students but also with academics for better understanding the needs for the labour market. All of business representatives agreed with this point. They offered the following cooperation ways as academics' visits to companies and business managers visits to universities; joint projects; academics' involvement in creative workshops organised in companies; Brain Fights; University Open Days; the business section in University's Web page and etc. The business experts noted that it is important to act, i.e., to cooperate in any form.

3. CONLUSIONS

According to the accomplished research the majority of students are satisfied that they have economics and business studies and would like more subjects that educate and motivate their competency of entrepreneurship. This approach was accepted by academics and employers also. With reference to the results of the evaluation of psychological environment, it can be stated that students are enough satisfied and feel psychologically well studying economics and business subjects. A good psychological climate during time of lectures helps to master the study material much better. The performed survey revealed that the majority of engineering graduates have sufficient knowledge of speciality, but their employment opportunities are limited by the lack of practical skills, economics and business knowledge. In summarising the employers' attitude to the young professionals, it can be stated that new graduates lack of common competences as skills of introducing themselves, communication skills, courage in making independent decisions. In addition, according to the business representatives, most of them do not have personal ambitions with a professional activity and are minded to change workplaces frequently. The issues of motivation, the pursuit of the objects and self-control of young professionals remain relevant for employers and for higher education establishments. The importance of economics and business studies in technological faculties was endorsed.

AN OUTLINE TO OPTIMIZE THE QUALITY ASSURANCE AND ROLE OF THE EXAMINATION COMMITTEES IN HIGHER EDUCATION

S.M. Gómez Puente

Education Policy Advisor, Electrical Engineering department
Eindhoven University of Technology
Eindhoven, the Netherlands
s.m.gomez.puente@tue.nl

ABSTRACT

Since the adjustments in the Dutch Law on Higher Education and Research Act in 2010, the Dutch universities have initiated an overall operation to optimize the mechanisms to monitor the quality assurance of examinations and the regulations. At the Eindhoven University of Technology (TU/e) in the Netherlands, the Examination Committees (EC) have modified their positions accordingly. The ECs in all Engineering study program at the TU/e operate in an independent and proactive manner and hold expertise in a number of fields such as legal, quality assurance, research and statistical analysis on quality of exams, among others.

Within this legal framework of changes the Examination Committee at the departments has taken an even more important role in monitoring and safeguarding the procedures. To strengthen the position of the Examination Committee new tasks and roles have been carefully defined. The EC is now to determine objectively whether the student meets the end qualifications of the study program and curriculum; to establish procedures and regulations within the Education and Examinations Framework of the department regarding the assessment and determining the results of examinations; to safeguard the quality of the organization and examination procedures, including Bachelor and Master thesis; and to take measures against fraud, among others.

In this paper, we will present a case on how the Applied Physics (AP) department has made changes regarding the quality of assessment specifically, and in general in the organization of the Examination Committee to accommodate the new demands by the law. We will outline how the AP Examination Committee has given form to its role to pay attention to assure the quality of examinations and assessment. In addition, we will explain with examples the methods used to research the quality of examinations.

Conference Key Areas: Quality assurance and accreditation; Curriculum development; Skills and engineering education

Hungarian engineering students' perceptions about their employability shortly before graduation

Anikó Kálmán[1]
Associate Professor
Budapest University of Technology and Economics (BME)
Budapest, Hungary
E-mail: kalman.a@eik.bme.hu

ABSTRACT

The aim was to explore the perception of engineering students of BME (Budapest University of Technology and Economics) on the competencies relevant to their employability shortly before graduation. The survey has been conducted in wider context in three European countries with the same limited number of interviews in a pilot project and the tendencies are being compared.

Following a literature review, in frames of a qualitative exploratory study, the engineering students have been asked about their expectations on future employment and perceived ability to meet the employers' requirements. We have analysed the discrepancy between the students' visions and the employers' needs.

Empirical evidence was collected on skills and competencies required by the companies from the point of view of engineering students. The students were interviewed and the talks were tape-recorded for further analysis. Students were chosen randomly, and so far, 14 students have been interviewed. Thematic content analysis was conducted to better understand the students' competencies.

The paper approaches what motivates students when starting a career. It is clear that both employers and employees claim that hard skills are needed, however, soft-business skills, known as interpersonal competencies would be vital too.

Conference Key Areas: Engineering Education Research, University-Business cooperation, Engineering Skills

Keywords: employability, competencies, engineering graduates, qualitative exploratory study

1. INTRODUCTION

In more and more countries throughout Europe, increasing attention is paid to the concept of knowledge-based economy, and within it, to the key role of higher education. Following the Bologna Declaration (1999), higher education has been considerably restructured, with its role becoming more appreciated. Research has proven that European universities have lately been forced to produce graduates who are able to adapt to the latest demands. (Molnár, 2016) The quality of graduate workforce is more and more in focus just like whether graduates are capable of meeting labour market demands. '*…In spite of all the efforts made so far, there is a considerable gap between the skills and competencies of new graduates, leaving higher education institutions and employer requirements…*' (J.A. & H.H., 2008)

In 2016, BME got involved in an international comparative study where it was interesting to experience that this issue does not only concern the students of Hungarian universities of technology but also those of leading European ones. The objective of the research project launched in 2008 was to get a comprehensive picture of the competencies acquired by new graduates of technology. The repeated research launched in 2016 was a longitudinal continuation of the one conducted in 2008, completed with a comparative analysis between the participating countries.

The study involves three European countries: Great Britain, France and Hungary. This paper presents representative research data primarily with respect to Hungary. The target group comprises students of engineering shortly before graduation with focus on their employability, employment opportunities and demands. The students selected belonged to two groups: those participating in the traditional engineering programmes and those who aim for a degree in management parallel to their studies.

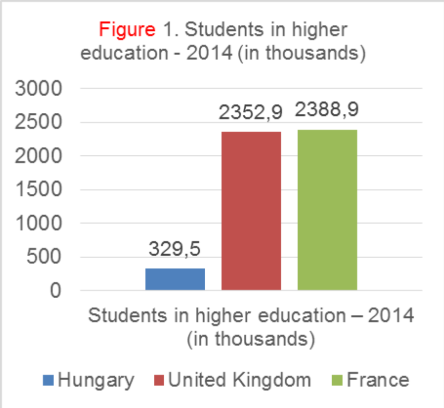
Graduating engineering students were asked about their visions, their employment opportunities and acquired competencies, and then it is investigated how this complies with the requirements of European employers. In the research, the empirical experiences of engineering students concerning employer requirements were collected. At the same time, it was also investigated what skills and competencies are needed for their successful career building. Finally, current tendencies are noted, and competency areas for development are explored.

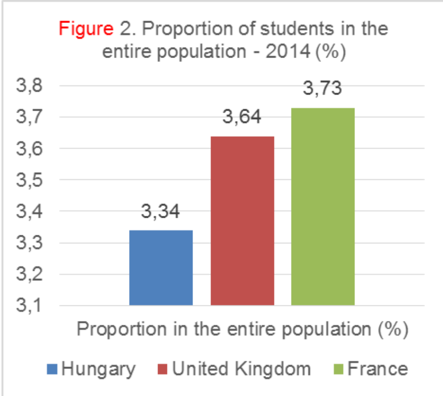
Research methodology applied: personal interviews were made with graduating engineering students using a structured questionnaire, which was identical in all the participating countries. After preliminary arrangements were made, interviews were planned to last 30-40 minutes, which turned out to vary greatly depending on personal motivation level and the individual's personality.

In the first 'pilot' phase, interviews were continuously made from September 2016, involving the adapting, editing and fitting the questions to the traditions of the country parallel with the analytic processing of the results gained. Following the recording of responses, results were analysed in view of the hypotheses.

1.1 Research background

Each of the three countries studied has a quite different higher education structure. In France and Great Britain, about the same number of students (2.4 million) take part in higher education programmes while in Hungary, there are approx. 330,000 students in higher education (see Figure 1). If the proportion of students in the entire population is considered, the difference between the countries is no longer big.





(Source of data: https://goo.gl/8pdVXK)

There is a slight difference in the data amounting to some tenths of percentages in the proportion of students in the three countries. Parallel with this, it is important to reveal what requirements employers have throughout Europe towards the newly graduated. *'In order to be able to define student employability, both their personal and knowledge-related skills should be explored.'* (Knight & Yorke, 2004)

1.2 Hypothesis

In formulating our present research hypotheses, we relied on 2008 research results, and formulated our assumptions accordingly. Engineering students formulate more clear and concrete ideas so they apply for fewer but better definable jobs.

It was also assumed that engineering students apply for fewer jobs and spend longer time with a single employer than their peers who completed a parallel management programme, and that the amount of salary is an important consideration for them in job-seeking. It was also expected that in the field of skills, time management, communication and teamwork will require the greatest development.

2. RESULTS

2.1 Career intentions

Most of the volunteers are not actively seeking jobs at present as many of them are already working in some form or other. It is common that future graduates choose one of the companies more closely attached to the university for their internship but after earning their degrees, almost each of them would like to find another job.

The overwhelming majority of the interviewees want to go on working in Budapest or near the capital (Pest county) in any case, and none of them would like to spend more than 2 hours/day commuting. Several of them would like to move to a suburban area near the capital. There was only one volunteer who thought that the location is not important for him as long as accommodation costs are covered by the employer.

Almost all of them wish to try working abroad, many only for the experience, for just a few years but there are also students with much more serious plans: they aim to set up a company abroad and move there with their families. Those who considered having an international career had it in common that they would only go to western countries. Germany, France, Canada, the USA and Finland were mentioned as potential destinations (note that the last one is geographically in the north).

On the basis of the pre-formulated hypotheses, I expected the amount of salary to be an outstandingly important consideration for jobseekers. The first significant difference between technical managers and ’traditional’ students of technology was revealed with this question. Technical managers considered the amount of salary much more important. They have not applied for jobs or accepted offers if they feel that their knowledge is ’worth more’ than the amount offered. In contrast, this is not yet a key consideration for most of the engineering students at all. They are much more concerned with the ’nature’ of their future jobs and the opportunity to gain experience. Some interns said that their salaries were ’ridiculous’ despite the fact that they spent a relatively long time at the workplace in addition to studying. As they said, this approach of theirs is likely to change after they earn the degree, and will only seek jobs above a certain minimum amount of salary.

The survey also revealed that many of them also seriously considered accepting jobs far from their original fields. For many, the working schedule and the workplace atmosphere are decisive factors: they prefer part-time jobs, and a good and direct relationship with the superior and the colleagues. As a demand, several respondents mentioned the methods already widespread and proven in Northern Europe, which could have a motivating effect on new employees, e.g. free coffee, kitchen use, ergonomical, modern working environment and free Fridays. ”*In the Norwegian culture, it is particularly important to strike a balance between work and life. They rather have the ’We work to live’ than the ’We live to work’ approach therefore they finish work very early on Fridays.”* (New In Norway - http://www.nyinorge.no)

2.2 Job seeking

Most of them have started to apply for jobs relatively late, only during this year, mainly in order to complete the obligatorily required professional practice. There are only a few students who have already been working for years: they typically started to submit applications before or simultaneously with starting their university studies.

The Internet is regarded to be the major source of job advertisements. Facebook and www.profession.hu are two of the most preferred websites. Almost everybody was aware of the functions of the LinkedIn page although few had actually used it before. They are considering actively using the page in the near future as they think it is a network with many advantages. They regard it to be the ’Facebook of jobseekers’.

In addition to the webpages, the different job fairs were mentioned by many as an opportunity for orientation. However, opinions were mixed about their usefulness. Many only go there to look around and see the different employers. Many consider it a problem that in job fairs, companies place professionally unprepared people in their stalls, who may not show empathy towards jobseekers as they often have no idea whatsoever about the students’ knowledge, skills and professional fields.

When asked about jobseeking strategies, most of the respondents said that they apply the proven tips and tricks, and are afraid to deviate from them, let alone develop a new strategy of their own. Some of them think that they will certainly get a position if they know somebody who already works or has recently worked for the company. Those who have such a connection have so far had 100% success when applying for a job, and they consider it likely that they will make use of their connections on other occasions, too. To quote one of them: *'You have a straight path if you know somebody... Unfortunately, this is the only safe method nowadays.'*

Before starting the interviews, I thought the majority would want to work for a multinational company but the results showed a completely different picture. Most of the respondents completed their internship in a multinational company. In the future, the vast majority of the interviewees would not like to work for giant companies. Some would like to start their own enterprises. Many regard multinational companies as an opportunity to gain experience but many realized that a smaller company might also be suitable for gaining the same kind of experience.

The second significant difference between engineering students and technical managers was revealed in the number of the applications submitted. So far, respondents have submitted 25 CVs on average but the technical managers have submitted many more applications than engineering students. It was typical for engineers that the number of their applications submitted varied between 1 and 10. They tend to spend a long period with one employer as a frequent change of jobs is not at all typical of them. On the other hand, the same number varied between 70 and 110 for technical managers. They are characterised by frequent job changing as they make use of the best current offer. They regard themselves as experts who the employers need. Consequently, if they are dissatisfied with something, they leave their current jobs without any scruples and start jobseeking again.

It was typical that the students had about 70% as many interviews as the number of their applications submitted. Most frequent types were telephone and personal interviews which meant a positive experience for them. Only one respondent spoke about going through several rounds of interviews, where English language competence was in focus. It is typical that a significant proportion of the interviews were conducted in an informal atmosphere. Those students who also talked to the foreign managers of the company almost had the impression that the atmosphere was friendly so their previous fears generated by gossip and beliefs proved to be totally unfounded. Following the job interviews, only one student asked the employer for feedback. The others considered it enough feedback whether they had been hired or not, and were not interested in any underlying reasons. Some of them received some unsolicited suggestions to help their development. Two volunteers only realized during our interviews that some feedback from the employer would have been useful for the future and expressed their regret about missing out on this opportunity.

2.3 Competencies

Many thought that professional knowledge, adaptability, language proficiency, flexibility, problem solving and good communication skills belong to the competencies/skills which are most required by employers. Irrespective of faculty, volunteers were of the opinion that only their basic disciplinary knowledge must be extremely solid because students have diverse interests and therefore believe that they acquire the necessary skills/competencies by working for various companies.

Despite agreeing on the crucial role of adequate professional knowledge, they differ sharply in their opinion about the rest of the programme depending on which faculty and which field they belong to. Students of technical management and environmental engineering thought that the knowledge they acquire during the training is far from sufficient. They think that discontinuity is one great disadvantage of the programme;

they just touch upon each professional field, which means that they do not obtain a comprehensive picture or deeper knowledge of any field. This they thought may create obstacles after graduation. This problem is further aggravated by the fact that employers have no idea about the enormous differences between two technical managers graduating from the same institution. Furthermore, it poses further problems that a retiring technical manager cannot be replaced by a newly graduated one owing to the differences between the various training programmes and the lack of expertise. This problem could be solved if they chose a specialisation much earlier as most of them know very well by the end of the first year which fields they would like to pursue and which ones fall outside their sphere of interest.

The results of the interviews supported my assumptions about time management. With the exception of a single student, each pointed out time management as the field in need of major development. In their own view, they are likely to procrastinate, especially at home where they are under no direct supervision. There were, however, some who would be scared of flexitime working hours due to procrastination. As they said: '*if I were given freedom, I might delay everything so much that I wouldn't even get to my workplace.*' *'Procrastination is the vice of human life…' (Dr Ildikó Takács)*

As a cause of procrastination, many identified the unpleasant nature of the task or the constant fatigue they suffer from during the semester. They find it difficult to start working on the task. Many also find it hard to maintain continuous focus, and they do not know how to improve in this. They all agree that this ability of theirs has changed considerably during their university studies, but they do not find this sufficient.

The second most frequently mentioned field to be developed was communication skills. The reason for this was seen in the special nature of the programme, which requires in 90% of the cases individual work from students, and they rarely need to give presentations. This problem leads straight to the third most problematic shortcoming, i.e. teamwork. Many thought that at the beginning, they would find it hard to work in a team because communication between team members would be difficult and university studies did not prepare them for this. Among mechanical engineers, preparation for teamwork has become more and more widespread, which means that students must solve problems in small teams. They favour this practice because instructors can devote more attention to each student and these tasks are considered much more 'lifelike'.

The fact that they are struggling with the above shortcomings is of particular interest since the respondents completely agreed on the utmost significance of good communication skills, and that of the ability of presenting and promoting themselves and being convincing. To summarise the opinions, having good professional knowledge was considered most important alongside the ability 'to sell themselves' as well as being proficient in English and presentation skills (even in English) while German language skills were considered an advantage.

Similarly, everyone thought their individual skills had developed greatly in the last year. They especially stress that subject courses were much more professional and field-specific. This was when the components started to fall into place, and the bachelor programme courses, the necessity of which had been questioned before, started to make sense. By the end of the BA programme, most emphasised their development in presentation, communication skills and time management. Generally, they found the last two semesters of the seven-term programme the most useful.

2.4 Employers' views on competencies

The tendency to almost exclusively hire graduates for vacant or newly created posts is becoming increasingly characteristic of European employers. This tendency is discernible in Hungary, too, in the various job advertisements and in the statistics provided by the Central Statistical Office: in 2015 in Hungary, 82.1% of those with a higher educational degree were in employment, while it was 69.9% of those who had secondary level qualifications and merely 47.1% of those with no secondary school leaving certificates (Hungarian Central Statistical Office, 2015).

Employers give the following reason for their preferences: *'Skills and competencies which graduates acquire during their university training are especially important.'* (UK employer) *'We prefer graduates because they are able to understand and analyse complex facts.'* (Slovenian employer) (J.A. & H.H. Graduate Employability…)

Moreover, graduates are considered much more mature who need less supervision and can accommodate and adapt to the work environment. *'Having studied at degree level makes them more mature… and more employable.'* (UK employer) *'Someone who is flexible and who has the ability to prove themselves*.' (Romanian employer)

In recent years, employers have experienced that the knowledge of newly graduated technical professionals has been lacking in the fields of business and social sciences. This is why they give preference to graduates who have also had such training during their university studies. Furthermore, employers require excellent communication skills in addition to professional knowledge, and the ability to work in teams. Often, however, graduates do not meet these requirements. Employers suggest that by requiring students to do more 'compulsory' teamwork during their studies, students could overcome the lack of communication skills and learn how to work in teams.

3. CONCLUSION

Although the research is still ongoing, some results have already become clear:

Students of engineering are much less interested in the amount of salary they can get than the students of technical management. The former consider obtaining experience as well as studying of primary importance but they think that in the future, they will probably attribute more significance to the amount of money they can make.

Both 'traditional' engineering students and technical managers struggle with time management issues. Many make the mistake of underestimating the time required for a certain task. Many have the problem of procrastination, sometimes they suffer from a lack of motivation to carry out a task. Most often they experience the negative consequences of this: they run out of time during the day, which they try and adjust in the evening, which in the end has a harmful effect on the amount and quality of sleep. Another problem is that many do not have the communication skills employers require. Most European companies are looking for innovative graduates with ideas and initiatives, who are proactive and driven by the wish to bring about a change.

Engineering students submit considerably fewer job applications than their fellow students of technical management. Characteristically, they work for longer periods of employment at a workplace and do not want to change jobs if not necessary. In contrast, technical managers like variety and wish to try themselves with different employers of various kinds. They often look for a new job if they are dissatisfied with something. In some cases, they change jobs every few months.

Gamification to engage engineering skills in technical higher education: an experimental approach

Mark Stappers

Randy Kerstjens

ABSTRACT

The mechatronics industry is fully under development in every area. With the upcoming era of Industry 4.0 things will change in the industry. While the industry is focussing on being ready for the industry 4.0, also the universities are preparing students for this new era. Projects inside the university are very important for creating the attitude and skills that are required, where the V-model (VDI-2206) is used as designing technique. Systems engineering is more than applying the V-model, it's also having the right mind-set and attitude in the various phases during a project. In the first year of the mechatronics department students need to apply systems engineering in the projects, where the age of the students are between 16 and 20 years. In the first years project called, "Smart Industry Mechatronics (SIM)", gamification is used as an experiment to optimize the systems engineering process, where students and teachers are getting familiar with the world of Industry 4.0, and to use and optimize the talents of the students. This paper describes the process and methods that are used for implementing gamification inside the SIM project.

Conference Key Areas: Mechatronics, Systems engineering, Gamification

Keywords: Mechatronics, Systems engineering, Gamification

INTRODUCTION

Industry 4.0 is currently the trend in automation and data exchange in manufacturing technologies [1]. Industry 4.0 describes cyber-physical systems and combines them with technologies like the internet of things and cloud computing. By applying these techniques it's possible to create a "smart factory". In the Netherlands the industry 4.0 is called "Smart Industry" [2].

For education it's important that students can combine knowledge with technical skills. The University is applying systems engineering as a way of working during projects. Students cooperate in project groups, with different roles and tasks. In 2013 the department of mechatronics did a project with local industrial companies to find out which way of working needs to be implemented in the education. The outcome of the project is that students need to apply a systematic approach that covers all the aspects during a project [15]. From the results of this project, the university has chosen to implement the V-model [3] inside their mechatronics projects.
Students who start at the university of applied sciences have minimal knowledge about the latest techniques and designing methodologies. To engage the motivation of the students, gamification is used in the first years to do research about the technical aspects and to learn and to implement technical knowledge in the project combined with systems engineering.

1 SYSTEMS ENGINEERING

One of the greatest stumbling blocks during any product development is the enthusiasm demonstrated by group members who, after reading the assignment, immediately set to work on construction, only to discover at a later stage that they have forgotten something. The more advanced the stage the project has reached, the more complex and the more expensive it becomes to still make changes. It is therefore extremely important to work systematically during the development process. As improvements are achieved in the way in which the steps are taken, the project will advance more smoothly, and at the end you will reach the finishing point faster. However, the most important point is, that if you work through the steps in the V-Model correctly, you will arrive at a guaranteed good design.

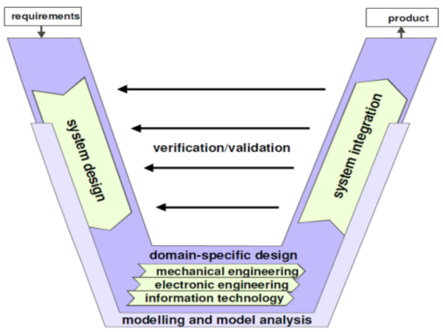

Fig. 1: General overview V-model

The input for this model consists of the requirements of the assignment given to develop, these are the user requirements and system requirements. On the left-hand side of the V is the system design. In other words, here is determined what the system will look like. Here is decided which issues will be solved through mechanical engineering, which through electronic engineering, and how the relationship and communication between these disciplines will be structured. At the bottom of the V-model, the actual development process takes place. The mechanical components take on their real form. The electrical components are selected and designed. The logistics (software, protocols, instructions, etc.) that enable all components within the system to function and communicate are described. However, because this is an industrial standard, it also simultaneously considers the manufacturability, the distribution of the products around the world, the useful life, the maintenance, etc. A product of which a million units are to be produced must be designed differently from a product of which just ten are to be produced. A product that needs to last 10 years will be designed differently from a product for a single use. One can imagine that with an extremely costly product, suitability for repair is more important than for a relatively cheap product.

On the right-hand side of the V, implementation, testing and checks are carried out. No matter how hard the designers try, every design always contains some errors.
This model is therefore produced to provide an answer to the complexity involved in mechatronic systems. Within the university projects, however, far less emphasis will be placed on reproducibility, investments, maintenance, etc.; instead, more focus will be placed on the single production of a functioning model. We have therefore somewhat simplified the V-Model by specifically designating the steps which must be taken.

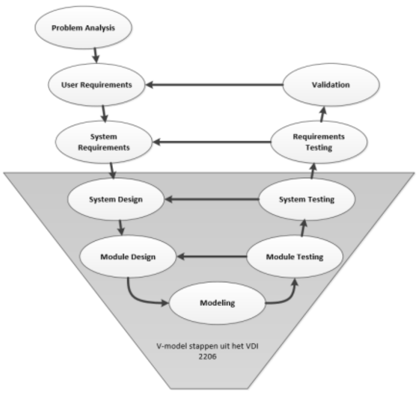

Fig. 2: Simplified version V-model.

2 GAMIFICATION

Gamification is a relatively new term, but the concept of gamification is not new. Gamification is used for all kinds of different purposes. From training purpose for economics, till education purposes, but gamification is never used in relationship till systems engineering.

The term gamification has many times been defined by various persons. The most commonly accepted of gamification is “Gamification is the use of game mechanics to non-game activities in order to influence people’s behavior” [4].

Game mechanisms are constructs of rules and techniques that are used for implementing gamification. Typical game mechanism that can be used are: points, levels, challenges, trophies, badges or achievements [11] .

A second game technique that guides and motivates players are game aesthetics. Game aesthetics are the desirable emotional responses from the player while he interacts with the game. Emotions like fun, trust, surprise and satisfaction are able to drive action and engagement [6].

To integrate gamification in systems engineering it is crucial to understand why and how mechanisms to positively influence people. To understand these mechanisms models of motivation and behavior from the field of psychology needs to be investigated. Wu (2011) analyses Maslow hierarchy of needs [8], b.F. Skinner’s behavior model and Csikszentmihalyi's Flow theory [9] and concludes that needs and motivators are similar to game dynamics and mechanism [8] .

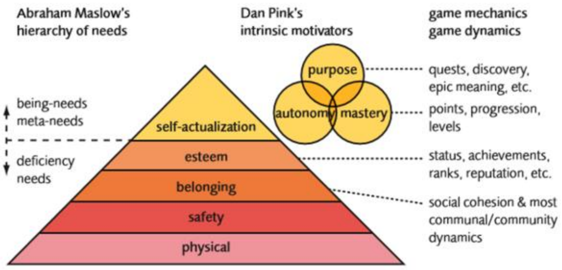

Fig. 3 Maslow/Pink Model – created by Micheal Wu PH, scients Lithium Technolgy (Wu, 2011)

According to Beza, gamification techniques needs to be done in an well-defined environment [6]. The main question that needs to be answered for applying gamification is: "What kind of behavior do you achieved, and how are you going to implement that" [11].

3 FOGG BEHAVIOR MODEL

For implementing gamification several canvas models can be used as a base platform [14]. However a lot of canvas models can provide a lot of details which can be used for setting up the game. For the SIM project, the fogg behavior model can be used as a starting point for gamification [12]. The fogg behavior model shows that three elements must converge at the same moment for a behavior to occur: motivation, ability and trigger, as can be seen in figure 4. When the Fogg Behavior Model (FBM) is used as a guide, designers can identify what stops people from performing behaviors that designers seeks and it also helps academics to understand behavior change better.

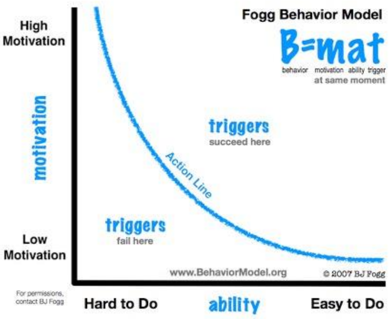

Fig. 4   Fogg's behavior model, created by dr. BJ. FOGG

The FBM highlights three principal elements, motivators, simplicity factors and triggers. These three elements have all specifically subcomponents. According Fogg, triggers might seem simple on the surface, but they can be powerful in their simplicity.

The FBM has three main elements, one of which is Ability. In order to perform a target behavior, a person must have the ability to do so. According Fogg designers of persuasive experiences sometimes assume people have more ability than they really do. There are two paths to increasing ability. You can train people, giving them more skills, more ability to do the target behavior. That's the hard path. The better path is to make the target behavior easier to do. Fogg calls this simplicity [12]. In his behavior model sometimes the term ability can be swapped with the term simplicity. Ability is the correct general term in the model, but in practice simplicity is what persuasion designers should seek. By focusing on simplicity of the target behavior you increase ability. Simplification of the assignment is necessary to keep the motivation and the right window according Fogg's motivation. The third element of the Fogg Behavior Model are triggers. Without a trigger, the desired behavior will not happen. Triggers can be useful to activate a human behavior. Triggers can be external, like an alarm sounding. Other times, the trigger can come from our daily routine. An effective trigger for a small behavior can lead people to perform harder behaviors. According Fogg, it's a natural chain of events that an effective trigger puts into motion [12].

According Fogg, simplification of the assignment is necessary to keep motivation. Simplification is only needed when the ability doesn't match with the expectations and the chosen triggers. The SIM project is using several types of simplification, so that groups can go through all aspects of the V-model.

Groups are formatted by the project coordinator. The groups exist between 6 and 8 persons. The groups are formatted inside a class, with a maximum of 32 students in class.

4 FIRST YEAR PROJECT MECHATRONIC

The department of mechatronics, of the university of applied science has strong connection with the high-tech industry. Most of the graduated students will be junior employees in those companies. That's why the systematic approach behind a project needs to be developed on the university. The main goal of the first years project of the mechatronics department is that students, needs to cooperate in several project groups and get familiar with process that's behind the development of a mechatronic system. The first years project theme is the “”Smart Industry”.

The curriculum of department of mechatronics contains four quarters. Every quarter exist of 10 weeks. The duration of the whole SIM project takes 30 weeks, where the projects is divided in three parts; SIM1, SIM2 and SIM3. The total amount of European Credits are given with by every project, and the total workload for every student is 15ECTS divided over these three periods.

To optimise the maximum result out of a project group a competition can be very useful. Competitions as First Lego League (FLL), First Robotic Competition (FRC) and Robocup are examples whereby technical assignments inspire students [10].

For the SIM project 25 teams will compete in game. The game is to create an autonomous driven vehicle which is capable of picking up objects and to place the objects on a scale. All the weight that is collected and placed on the scale will result in points. The groups have a maximum of 5 minutes to collect as much as possible weight.

The use for gamification inside a project is to stimulate a certain behavior. Focussing on the process will result in a better product of the group. In SIM1 the group must realise an autonomous driven vehicle which is capable of following a black line on a white surface.

In SIM2 the group needs to develop a gripper which is able to pick up objects from the floor, place them on the vehicle and eventually place them back on the floor. The technical specifications are given at the beginning of SIM2. In the game more advanced grippers can be rewarded if they are capable of picking up objects from various heights and distances. In SIM3 group needs to integrate the solutions of SIM1 and SIM2. In SIM3 the assignments of the SIM1 and SIM2 are placed in a different context.

At the start of the project students have mostly no idea how to start a project or what to do. This often results in a slow start of the project, and that generally effects the final result. Gamification techniques can help groups at the start of the project, but it gives tutors also the possibility to give feedback earlier in the process.

5 IMPLEMENTATION SIM PROJECT

For the setup of the SIM project a canvas model is used [13]. To make this project functional and fun, the theme “Smart industry” is chosen. By adapting this theme students will automatically try to make a link with the new industrial era. Groups will work on different assignments in SIM1 and SIM2. In SIM3, the parts of SIM1 and SIM2 will be integrated in a final product. Another requirement was that “systems engineering” was applied in every SIM-project. The implementation of the game mechanism is bounded to the environment of the university of applied science.

The university environment facilitates workshop areas, a shop, meeting rooms and workplace per group. In the mechanical workshops students can work under supervision on machinery or can print 3D components in our print lab. Other mechanical and electronics parts can be ordered through a shop. A group gets a fixed budget per quarter, which can only be spend within the FHENG environment. For general meeting purposes FHENG facilitates several meeting rooms for groups. Having special meeting rooms makes it possible to have a weekly meeting between a group and a tutor. By having all these facilities, the university environment simulates the industrial way of working on a very basic level.

As described, the main goal during the SIM project, is that students learn to work in a team and to develop a systematically approach for developing a mechatronic system. To optimize the workflow, groups needs to get familiar with the university environment. This means that at the begin of the SIM project, the focus of the project is more in exploring the environment and to see what is possible inside the environment, then on the technical product. Once the group knows what is possible inside the environment to group can think about setting up the technical requirements.

The mechanism of the SIM project is based on the V-model. Groups can go through the V-model by doing task in levels. The V-model is divided in ten levels, as can be seen in Figure 5. After every phase of the V-model a new level is introduced. On this way the tutor is able to give earlier feedback.

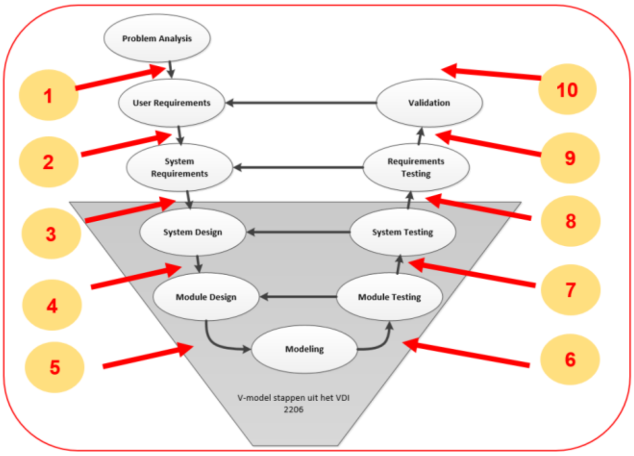

Fig. 5: Simplied V-model linked to gamification levels

At the start of the SIM project students have a basic knowledge and are unfamiliar with the habits of procedures inside a new school. In that perspective the scope of SIM1 is in the early levels of the project not only focussing on the technical aspect, but also exploring the environment. In SIM1 and SIM2 students get a full description of what to do. In SIM3 groups are familiar of the way of working, and need to merge the solutions from SIM1 and SIM2 in a final solution. If the solution of SIM1 and SIM2 doesn't match the requirements, groups can improve or fix their solution in SIM3. In this way groups can learn from making decisions by analysing the process. Early made decisions can have a huge impact on the final product. Analysing the process can result in new insights on how to approach a problem and how to improve the quality of the process or product.

The triggers are used to go to next level. In the SIM project the triggers are divided in four categories: general tasks, technical work, documentation and evaluation. In every category groups can score points by doing tasks in every category. Per level you groups can earn maximum 20 points. For every average task, one point can be earned. Complex tasks, or larger tasks, can be rewarded with multiple points. To align the triggers with the ability and talents of the students, a mechanism is created. Groups can go to the next level by succeeding a couple of tasks in every category. This means that there are more tasks written than needs to be done. Triggers works best, when a group believes they are in control. Having options means that group can control the situation. By creating multiple categories, the group can control the situation on several elements. By doing different tasks, students can create their own route to reach the next level.

Triggers can help to increase the ability, but in some situations the needed ability is too big. In these kind of situations simplifications can be applied to a certain task. Other possibilities in this model is that the minimum score that's required for every category can be adapted.

To insure that groups can finalize every project, simplification of the main goal of every project is necessary. Simplification for the SIM project where mainly technical simplifications. In SIM1, for the autonomous driving, all basic hardware was provided by the project organisation. The basic hardware consist of, a vehicle, a microcontroller, a H-bridge for controlling the motors of the vehicle and a battery. To make it easier to realize an autonomous vehicle, a black line was taped on a white surface which they could follow.

In SIM2 essential information about grippers and mechanics was provided. This was for Increasing the technical spectrum of the students and to stimulate them. In SIM3 no technical simplifications where introduced. Chosen concepts in SIM1 and SIM2 need to be integrated, fine-tuned and tested in SIM3.

During the SIM project a weekly meeting took place with the tutor. The tutor monitors the process of the group and gives feedback about the tasks. In these meetings the students simulate a company meeting and the tutor will be there as an observer. During the meetings the tutor can decide to give feedback or feedforward information to the group.

6 CONCLUSION

A canvas model can be used for setting up a technical project where gamification techniques are integrated in a systematic approach. One of the key elements to successfully wrapping up a project is the project environment. The university has an environment which simulates processes inside a company. These facilities contribute to the behavior of students and how to approach tehcnical projects. To keep students connected with the industry, the theme "Smart Industry" is chosen for the first years mechatronics project. The smart-industry theme was leading for setting up the technical roadmap for the project. The project is divided over three projects. The results of the first two projects will be integrated in the final product. In every project groups needs to work with the V-model. The gamification techniques are mainly applied on the systematic approach. The V-model is divided in ten levels. Going to the next level can be achieved by doing tasks. Tutors evaluate the levels. By creating ten levels, ten evaluations moments are created. This lead into earlier feedback from the tutor and groups that know what to do. By applying gamification in the SIM project, we experienced a positive contribution to the development of skills, attitude and knowledge for the first year students.

ABSTRACT

This paper discusses the evolution of an active learning assignment [1] for second year undergraduate biomedical engineers. An arc of assignments throughout the first two years of their study supports their understanding of the design cycle and aids in assimilation of material taught in lectures and more structured laboratory workshops [2]. The assignment – to create an item of 'smart' clothing for an athlete – was primarily designed to reinforce student learning in the areas of physiological monitoring through transducers, basic electronics and Arduino programming.

A misalignment was observed between teaching staff's preconceptions of students' skills and knowledge, and the experience that the students actually bring to the assignment which influences how they approach the work, echoing the concept of the hidden curriculum [3]. This led to the team aiming to improve support of students' skills in debugging, their awareness of laboratory health and safety and links between different strands of their education through pre-assignment material, changes in teaching vocabulary and small changes in assessment. The impact of the changes has been evaluated through teaching team discussions and analysis of short pieces of individual reflective writing done by every student as part of their assessment before and after the material's introduction.

Conference Key Areas: Engineering Education Research, Curriculum Development, Skills and Engineering Education

Keywords: Professional engineering; design; group project.

1 INTRODUCTION AND BACKGROUND

1.1 An active learning assignment

A key enabler for undergraduate students to make the transition from passive learner to competent practitioner can be to support the development of their problem solving and design skills through active learning [1]. This can be done through providing open-ended design projects structured to support the arc of the design cycle [4]. We have done this during our engineering undergraduates' first two years through a series of six week-long assignments that consolidate engineering knowledge taught prior to each assignment while encouraging students to apply their new knowledge to an open-ended design task [2].

For this assignment, Biomedical Engineering students work in groups of three to use wearable Arduino technology [5] and a free choice of electronic sensors and outputs to create a prototype item of clothing that will monitor an aspect of an athlete's condition, chosen by the students, and provide an alert if an unacceptable level of injury is likely to occur. The published Learning Objectives for the assignment cover the students' knowledge and understanding of physiology, biomechanics, digital and analogue electronics and microprocessor programming alongside the professional engineering skills required to meet a design brief such as time and budget management and working effectively in a group.

1.2 Research methodology

We have followed an action research approach in the evolution of this student assignment and look at differences between two separate cohorts of students taking the assignment in consecutive academic years – known as cohort A and cohort B. Cohort A consists of 11 students who were set the unaltered assignment; cohort B has 21 students who followed the modified assignment one academic year after cohort A.

While teaching cohort A, the teaching team discussed problems they perceived with the students' approach to their work, and this discussion led to the reflection and research used in the process of developing the assignment that was then undertaken by cohort B. Our initial hypothesis is that the students were unaware of their apparent shortcomings in the perceived problem areas noted by the staff. This was tested by considering a short piece of reflective writing on the assignment that each student carries out as part of the assessment. These pieces have been analysed to assess the students' own awareness of the perceived shortcomings.

Changes were made to the assignment between the two cohorts to address the perceived problem areas and the effectiveness of these changes has been assessed both by discussions with teaching staff on their observations of the class and their views on whether this disconnect between staff expectations and the students' performance had been addressed, and by looking at the reflective writing from cohort B.

2 ACTION RESEARCH ON AN ACTIVE LEARNING STUDENT ASSIGNMENT

Second year Biomedical Engineering undergraduates work in groups of three for five days to fulfil a design brief to make an item of 'smart' clothing for an athlete that can monitor an appropriate physiological parameter of their choice and give a warning should that parameter fall out of pre-set safety parameters. The clothing should be safe, reusable, customisable and fall within a set budget. The students receive an introductory end-user design requirement and question and answer session with an athlete (an ultra-runner) before starting the assignment, and have previously had teaching on the design cycle, technical drawing, physiological monitoring, transducers, Matlab programming and digital and analogue electronics. The students have had no formal teaching while at university in Arduino programming, but some may have prior experience outside of their studies. The intended learning objectives are given in figure 1.

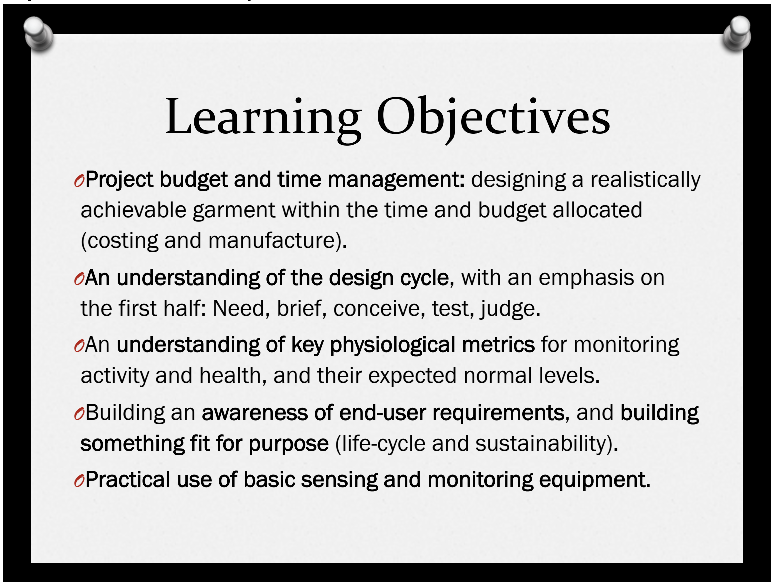

Figure 1. Learning Objectives given to the students before the start of the smart clothing assignment.

The assignment is the first very open-ended design and making project that the students encounter in their degree programme. Any type of clothing can be designed and built to monitor any parameter to give any signal so long as the students can justify how their choices meet the design brief. One student noted in their feedback:

"The [assignment] was by far the most fun I have had. The possibilities that we could have come up with were endless, only limited by time and budget" -Student B_6_2

Students are given access to the full range of facilities on offer in the undergraduate teaching laboratory and university maker-spaces. A wide assortment of electronics and sports clothing is available for instant purchase from the teaching team, but students also have the option of asking to purchase anything the laboratory does not have in supply. Adafruit Flora Arduinos have been stocked by the laboratory due to their robustness, wearable nature and the large amount of supporting code and maker projects available on the internet.

Between the two cohorts, the students have designed and built (with varying success) 2 pairs of pressure sensitive gait analysis trainers, 3 sweat concentration monitoring tops, 2 temperature sensing armbands, a temperature and humidity sensing top, a UV sensing cap, a core temperature and respiration rate monitoring sports bra and a GPS distance tracking wristband

Most groups chose to use coloured LEDs to indicate changes in the parameters they are monitoring.

Assessment for each cohort was based around the initial design, the end produce and short pieces of written work.

2.1 Cohort A pre-work and assessment

Cohort A received an introductory lecture for the assignment a few weeks prior to the week spent in the laboratory carrying out the assignment. This consisted of delivery of the brief, a presentation by a researcher working in the area of wearable assistive technology, and a discussion with a member of the teaching team who is a runner. The students were also shown two items of smart clothing developed by a previous student [6]. They received a list, and costs, of the electronic components readily available in the teaching laboratory and were told to research the available components and consider how they might meet the design brief. Links to information on Adafruit components and examples of wearable electronics were made available on the university VLE.

Cohort A's assessment is shown in Table 1:

Table 1. Assessment structure for Cohort A

Design Phase	*Decision matrix* using appropriate choices of criteria	5%
	List of physiological parameters the clothing aims to measure, and their expected ranges.	5%
	Design and estimated cost. A technical drawing full enough for someone else to be able to make your clothing	10%
Prototype Clothing	*Quality of prototype*, and closeness to meeting brief	30%
	Aesthetics – peer assessment	10%
Written report	*Full final costing* including broken components	10%
	Short reports on one area of: product life cycle, sustainability, scaling up manufacturing and costing	10%
	Individual reflection justifying any deviations from original design and plans. Reflections on how the week went and any changes that the student might choose to make if the process was repeated.	20%

2.2 Staff observations on Cohort A

Discussions with the teaching staff indicated that, on the whole, the class met the Learning Objectives shown in figure 1. However, staff felt there were shortcomings in areas where they had assumed students would be able to draw on prior experience of system troubleshooting and debugging, and be able to identify links between this assignment and previous classwork.

- All groups in the cohort, regardless of previous measures of academic ability (examination results and staff reports), attempted to completely construct and hard-wire their designs before testing any individual components and had to be encouraged regularly by staff to build their systems' complexity step-by-step rather than taking a 'plug and play' approach. The staff spent a significant amount of time teaching repeatedly concepts of basic debugging of coding and electronic circuits to individual groups of students.

- The students failed to identify the sensors available to them as transducers, despite having previously worked in structured laboratory sessions to characterise a set of transducers. The teaching team had to remind all groups of this work that they had carried out in the previous weeks, and encourage them to look back at their notes to draw parallels between the two assignments.
- The class also exhibited limited attention to heath and safety considerations when working on these self-led projects compared to the usual levels of conscientiousness that they adhere to in heavily structured mass cohort laboratory work. They did not appreciate that the use of un-insulated conductive thread would increase the risk of short circuits, and forgot very basic laboratory safety concepts (figure 2).

Figure 2. Students forgot basic lab safety, such as not jumping on a narrow piece of wood while attached by a cable to a laptop.

2.3 Changes implemented between Cohort A and Cohort B after discussion of staff observations

Changes were made to the preparatory work and resources given to the cohorts and some of the assessment was modified. The teaching team were also encouraged to use vocabulary echoing that in other parts of the undergraduate programme of study to reinforce links across the syllabus.

2.3.1 Preparatory work and pre-assignment resources

The introductory lecture for Cohort B again took place a few weeks before the assignment. The students did not receive the additional lecture from a researcher, but spent more time discussing the prototypes made by previous students and also received more instruction on the importance of health and safety and building a complex system in steps for ease of debugging.

Additional material was prepared by the teaching team and made available to the students on the VLE. This included:

- A guide to Adafruit wearables
- A quick guide to C++ Android programming showing common functions for Arduino
- A troubleshooting flowchart, with brief accompanying notes to aid in successfully producing working electronics.

Cohort B were told that cohort A had lost time during the assignment due to problems with debugging and understanding basic coding concepts, and were encouraged to read this material before beginning the assignment. They were also explicitly told that they would be using transducers and should revise any previous learning in this area.

2.3.2 Assessment

Much of the assessment for cohort B remained as in table 1. However, 10% of the prototype marks were allocated to the production of a plot of 'transducer characterisation' and 10% to 'health and safety' in an aim to use the backwash effect [7] to modify student behaviour regarding health and safety. Cohort B were not allowed to hard-wire any components until the teaching team had seen evidence of a transducer characterisation that indicated that a group had knowledge of the correct circuit required to obtain data from the transducer(s) of their choice.

2.3.3 Staff-student interactions during the assignment

The teaching team were encouraged to use vocabulary throughout the assignment that mimics the rest of the students' education – 'technical drawing' rather than 'design', 'transducer' instead of 'sensor', and 'digital electronics' rather than 'Flora' or 'Arduino'. Staff also ensured that the student groups had worked through the troubleshooting flowchart before offering assistance in the laboratory. These protocols aimed to encourage students to make links between their learning, and to facilitate movement towards independent troubleshooting and debugging.

3 RESULTS

The individual reflection written by each student as part of their assessment was used to appraise their overall awareness of the three areas of weakness perceived by staff: system debugging and troubleshooting skills, making connections to the rest of their curriculum and awareness of health and safety.

3.1 Cohort A

Cohort A consisted of 11 students in total split into three groups of three and one group of two. Seven (64%) students used the terms relating to debugging, troubleshooting, and iterative processes in their reflections. Three (27%) students mentioned other parts of their curriculum – two referencing transducers and one the design cycle. Three (27%) students mentioned safety and comfort of the end-user.

3.2 Cohort B

Cohort B consisted of 21 students split into seven groups of three. 13 (61%) students used terms relating to debugging, troubleshooting and iterative processes in their reflections. Nine (43%) referred to other parts of their curriculum – seven referencing transducers and two the design cycle. Nine (43%) students mentioned health and safety, although only one mentioned it in the general context of their groups work, with eight discussing health and safety purely from an end user context.

3.3 Staff perspective

Three members of the teaching team were asked to report verbally on their personal comparison of the two cohorts. Overall, it was stated that cohort B required 'less help' in debugging their systems and were more engaged in troubleshooting processes. However, it was also noted that the cohort did not appear to make copious use of the troubleshooting pre-assignment resources during the week-long assignment. Cohort B was reported to show a slight increase in their awareness with other parts of the curriculum. Staff reported no change in the proportion of groups, in their estimation, who lacked awareness of laboratory health and safety requirements.

4 DISCUSSION

Overall, this work has involved small cohorts of students: 11 and 21 in the two groups. This means that the statistics on the data are poor. An additional student adds 9% onto any quantitative values for cohort A and 5% onto those for cohort B.

We have made changes to the assignment reported in this work. However, it is possible that other university teaching staff have also made changes to the students' wider programme between delivery to the two cohorts that could also contribute to the changes in the students' skills and understanding reported in this paper.

4.1 System debugging and troubleshooting skills

Assessment of the students' written reflections shows no increase in phrases relating to system debugging and troubleshooting between the two cohorts. 64% of cohort A and 61% of cohort B use terms relating to this area. Staff reported that cohort B required less help in this area, but this has not been quantified.

It was noted by the teaching team that the students did not appear to regularly refer to the troubleshooting material provided by the teaching team during the week. It is possible that they read and understood the material prior to beginning the assignment. It is also possible that the act of introducing clear summative assessment for the transducer characterisation and not allowing hard-wiring of components before showing evidence for this assessment created additional structuring to the assignment that supported the students to de-bug before full construction of their prototypes.

4.2 Making connections to the wider curriculum

Cohort B showed an improved awareness of the links between this assignment and their wider curriculum. The ratio of those relating the assignment to the design cycle and those relating it to their transducers learning was ~1:2 for both cohorts. No student mentioned both the design cycle and transducers.

4.3 Awareness of health and safety

There was an increase in the awareness of health and safety requirements for the end-user seen in cohort B. However, staff noted no improvement between the two cohorts' general awareness of laboratory health and safety guidelines.

5 SUMMARY

This paper considers the efficacy of changes made to protocols and material related to a second year undergraduate assignment between the 2015/16 and 2016/17 academic years.

The assignment took place during the 2016/17 academic year with this new material and protocol in place. Staff noted that this class appeared to be more engaged with awareness of connections across their wider curriculum and debugging. No change was seen in awareness of laboratory health and safety. Reflective writing by the students showed no increase in discussion of debugging between the two cohorts, but an increase in discussions regarding links to the design cycle and classes on transducers, and a greater awareness of health and safety for end-users of their prototypes.

Action research will be continued for this assignment and further changes will be made for the 2017/18 academic year:

- The lecturers on the transducers course will be included in the preparation of this assignment with an aim to increasing integration between different parts of the overall programme.
- The teaching team will continue to highlight laboratory health and safety – pre-assignment quizzes in this area are being considered.
- We will continue to monitor the response of cohorts to troubleshooting and debugging, with an aim to facilitating a movement towards independent and confident use of these skills. One student stated:
  "I have primordially learned on the importance of having a vision by starting very simple. Breaking down the idea on multiple layers and starting with the foundation. Once that is working, you can add layers of complexity one by one.." – Student B_7_2

We aim to reach a point where the majority of students show awareness in this area.

We believe that, in a wider context, the work supports the concept of the backwash effect - the use of an assessment scheme that explicitly allocated marks for an awareness of a given area (in this case health and safety) led to an improvement in students' self-reported awareness of the area. The work also shows that integrating the vocabulary used by teaching teams across students' entire education can reinforce the process of making links between separate areas of learning.

6 ACKNOWLEDGMENTS

We are very grateful to the cohorts of students who took part in this study, and our teaching and education research teams especially Adam Gibson, Pilar Garcia Souto and Mikael Brudfors.

ABSTRACT

Current naval architecture curriculum in Taiwan focuses on building theoretical knowledge and scientific research skills through teaching mechanics and mathematics in the early years. It's believed that shipbuilding involves complex systems thinking and that therefore design should be engaged after one has acquired solid theoretical knowledge. Students struggle however to establish integrated understanding about ships from diverse knowledge sources and various learning methods. Architecture education, on the other hand, starts with introducing students to design and model making at an early stage and these topics retain emphasis throughout their entire education. Inspired by the restoration of an old Chinese junk, the authors wanted to investigate the relevance of wooden boatbuilding for modern naval architecture learning. We designed a hands-on curriculum where students built a western sailboat model following standard procedures. Students learned about modern timber, basic carpentry skills and could exercise their spatial intelligence. We also involved a highly experienced local shipwright master. Students have reported to gain integrated understanding of design, construction, material, mechanics, aesthetics, societal and historical aspects of wooden boats. The class has elevated interests in shipbuilding and facilitated active discussions about using wooden boat building as an agent for modern shipbuilding knowledge construction.

ABSTRACT

The importance of teaching entrepreneurial skills has been on the agenda for several years. But how do engineering education institutes (EEIs) serve as institutions facilitating the learning of these skills? In this study, we compare four EEIs from four countries located in two global regions, East Asia and the Northern Europe, in order to identify models for how education in entrepreneurship can be implemented according to each country's situation. We use a modified version of Dahlöf and Lundgren's frame-factor theory to analyse how the universities understand the internal and external driving forces for the development of this kind of education. We also address how these frame factors affect the development processes at each EEI. The study identifies differences in these processes, which depend on how pressures originating outside the universities are expressed.

INTRODUCTION

Globalisation, the digitalisation of society and other trends are expected to lead towards a different work situation for many people. A more turbulent work environment is expected, where more short-term jobs and project-oriented jobs are created and where people change work tasks more often.

This is one reason entrepreneurship has been on the agenda in education development for the past 20 years. Already at the beginning of the 1990s, OECD (the Organisation for Economic Co-operation and Development) published a report that pointed to entrepreneurial skills as a crucial ability for people who wanted to pursue continuous technical development (Blanchflower & Oswald 1998).

However, the entrepreneurship and enterprise are difficult to define. The entrepreneurship concept has its origin in an economic tradition and is derived from the French word *entreprendre*, which refers to an active person who gets things done. The Oxford Dictionary defines an entrepreneur as someone who 'sets up a business or businesses, taking on financial risks in the hope of profit'. Recent literature has extended this concept to cultural and social contexts (Skolverket 2015). A broader approach is also taken by Shane and Venkataraman (2000), who explained that entrepreneurship involves discovery, invention, creativity and, of course, ways of bringing the new ideas into a market. In an effort to cover all aspects of entrepreneurship, we refer to the general capabilities associated with entrepreneurship as 'entrepreneurial skills' and to the special capability of knowing how to establish a business as 'knowledge about enterprise'.

Over the past 20 years, enterprise education and the training of entrepreneurial skills have been the subject of a great discussion and debate in OECD countries. Strategic plans for entrepreneurship education at different levels of the educational system have been developed in some countries (Regeringskansliet 2009, Ministeriet för Vitenskap etc. 2010). Engineering-education institutes (EEIs) play an important role in entrepreneurial development; engineers often have positions in which entrepreneurship is a highly regarded skill, because they work in areas were technical development is moving very fast. The last 10 years have witnessed the formation of centres for entrepreneurship and enterprise and professorial appointments at engineering universities. These academic developments are meant to ensure that entrepreneurship is fully realised at the university level.

However, there is a lack of empirical studies that address how engineering education actually provides entrepreneurial education for engineers in a structured way. Although we have seen many examples of entrepreneurship courses, our impression is that entrepreneurship is not always taught in a coordinated, strategic and continuous fashion.

In this study, we take the first steps towards creating a model that can inspire and help EEIs to develop strategic and coordinated programmes for the teaching of entrepreneurial skills and enterprise. The model will be based on our comparison of cases from four countries representing two OECD regions. The case comparisons address how the EEIs in these countries include entrepreneurial skills and enterprise in their education. The two global regions in which the EEIs are located are very high-tech regions, but they are significantly different with respect to both educational and work culture.

The comparison will be conducted by analysing how engineering faculty, including both management and teachers, interprete the integration of entrepreneurial skills and enterprise from a university perspective. The analytical approach is based on the frame-factor theory. The results will be used to develop models for how engineering education can become a strong link in the engineer's development of entrepreneurial skills.

1. BACKGROUND

1.1 The frame-factor theory

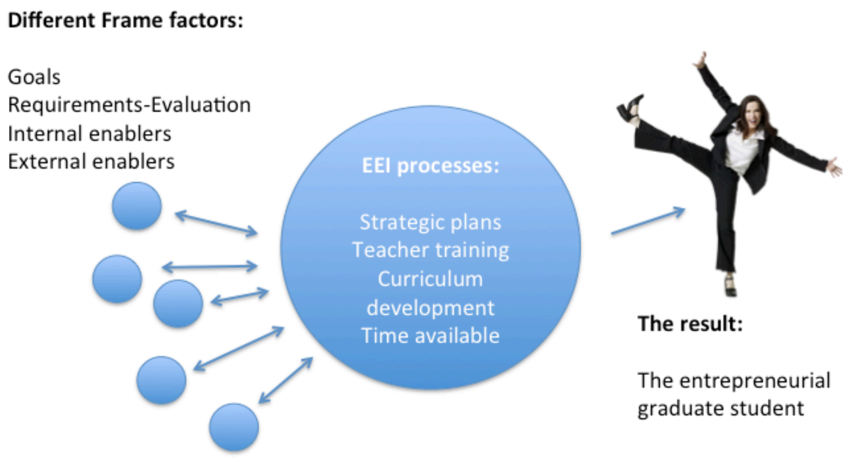
In this study, our perspective resembles the classic frame-factor theory, developed by Dahlöf and Lundgren in the 1960s and 70s (Broady, 1999). They used this theoretical framework to analyse the factors influencing teachers' teaching situations.

This theory posits that a teacher's ability to influence a teaching situation is relatively limited and is controlled by a variety of external factors that are difficult to change directly. Although we do not use the theory as such, it serves as an effective basis for our approach to the development of the teaching of entrepreneurship. We investigate the process of educating entrepreneurial citizens not through the eyes of the teacher, but through the eyes of the EEIs. The frames are seen as the factors of entrepreneurship education that EEIs cannot directly influence. These factors are defined in terms of each country (in this case each EEI) in order to create an awareness of which factors constrain the development of entrepreneurial-skills education at specific EEIs.

We investigate the processes undertaken? at each EEI to implement and run entrepreneurial or enterprise education. By studying the combination of these two types of factors, we hope to explain how and by whom the educational-development processes in this area are controlled.

In our approach, the *frames* are understood as the laws and regulations that affect entrepreneurship education and that enable engineering education. The *processes* refer to what is going on at the universities, such as faculty-training programmes, the development of strategic plans and the creation of good preconditions for the teaching of entrepreneurial skills and enterprise. The *result* is a student who has learned the skills necessary for becoming an entrepreneurial engineer (see Figure 1).

Figure 1: An overview of the described aim of the study.



2. METHODS

Two professors from the engineering faculty of each EEI were selected as informants for the survey. The EEIs studied were Aalborg University (AAU), Denmark, University of Tokyo (UT), Japan, Korea University (KU), South Korea, and the Royal Institute of Technology (KTH), Sweden.

In total, eight informants were included in the survey. One of the informants, the dean of an engineering department/college, represented high-level management. The other informants were professors engaged in the work of entrepreneurship education. A risk of the study was that the selected informants represented a group that had significantly greater competence in entrepreneurship education than other faculty members.

The faculty members were interviewed according to a semi-structered interview technique, in which a questionnaire was used as the question base. Each interview lasted about an hour.

Our analysis of the interview transcripts focused mainly on the questions associated with the frames and the processes taking place at each EEI.

3. RESULTS

3.1 External and internal enablers

In Denmark, the informants expressed the experience that society is changing. They described engineering as a field in the midst of a change in which more employees will work as consultants in smaller enterprises rather than as employees of large companies. This, in turn, requires that engineers be trained to handle this type of employment. The community in general has been aware of this change for at least the last 5–10 years, and a number of promotional activities have been launched during this period, including activities and competitions organised by various associations not related to the university. The informants also expressed a willingness to support the competence shift that needs to be achieved in order to successfully adapt to this change at government level. For instance, there has been funding for projects that can be applied for by individual teachers or teams of teachers in order to improve entrepreneurial and enterprise education. There have also been opportunities to apply for larger contributions that could be used to support broader changes in university education. Private donations were also mentioned as a basis for strengthening entrepreneurial education at universities.

In Japan, the informants gave a somewhat contradictory picture of the approach to implementing entrepreneurship education. On one hand, Japan has a strong desire to become more entrepreneurial, that is, to be a country where new ideas are developed and where new enterprises can start up. On the other hand, Japanese culture maintains in rather strong terms that it is almost impossible for a person to succeed after having failed, which means that in practise it is more favourable for engineers to work in the same company for the entirety of their careers. The informants expressed that companies would like engineers to develop more intrapreneurial skills; that is, companies would like EEIs to teach future engineers to play entrepreneurial roles within the company and to have the ability to develop new ideas that strengthen the company. As a result of the Japanese way of looking at career life, it is not really important to educate students in entrepreneurial skills and enterprise at the university level. In the future, this can be done at the companies themselves. The informants said that UT may be in a special position, because UT students quickly and easily get jobs at large, respectable companies. Therefore, the importance of having entrepreneurial skills might be more prominent in the context of a smaller university.

The government supports initiatives like EDGE-Global and Entrepreneur-Dojo, which are global venture activities in which engineering students can participate. The problem with these activities and competitions is that they do not give university credit and are therefore seen as less attractive by the students.

In Korea, there is strong external pressure to develop entrepreneurship and innovation competencies in engineering education. Industry has influenced this process by exerting strong pressure to improve this part of engineering education, which in turn has prompted the government to see entrepreneurship education as very important. The informants described government support for student venture competitions and projects designed to strengthen engineering education as such. In South Korea, there are also some mechanisms of direct control. In the accreditation process for engineering education, universities have to show that they offer courses on entrepreneurial skills as capstone design courses. There are also upcoming plans for the government to link funding of research based on the presence or absence of entrepreneurship and innovation education, often referred to as capstone design courses, in which social issues are dealt with in teams, together with industry/society.

The Swedish informants expressed disappointment regarding the development of entrepreneurial and enterprise education. The topic has been on the agenda for many years, but without being lifted to the next level in engineering education. There is undoubtedly pressure from industry and other associations, as is evidenced by the many activities—such as competitions for students—that are supported by companies or associations. Swedish industry also sees intrapreneurship as an important part of the development of those skills, which means that there is a desire and a need for these kinds of skills within the companies.

A popular initiative funded by a private foundation in Stockholm, the Stockholm School of Entrepreneurship Education, is partly devoted to engineering students from KTH but has the overall aim of strengthening entrepreneurship education for students from different areas. The informants did not see the government as directly supporting the development of entrepreneurship in engineering education, but there is authority that holds money for investing in entrepreneurship in Sweden through available research funds.

3.2 Processes within universities

At AAU, in Denmark, problem-based learning has been the basis for education for a very long time (Xiangyun et.al. 2009) This pedagogical methodology fosters some of the entrepreneurial skills to be developed over the course of the students' education career, because students work in teams with companies closely linked to their projects. Despite this fact, the informants expressed that faculty do not necessarily know how to educate students about entrepreneurship. Most faculty members have never worked outside the university, and therefore they most often lack 'real experience'. The aim at AAU is to give all engineering students the opportunity to learn entrepreneurial skills and enterprise, but the university's strategy for developing entrepreneurial competence is not yet clear. It may include hiring teachers from industry and/or training faculty already at the university. AAU has a centre for innovation, where engineering students can take elective courses in entrepreneurship, which often include learning outcomes such as competencies for developing a new idea and building a start-up company. The students frequently take these courses. The university also runs a master's programme in entrepreneurship, in which students work on, among other things, innovation ideas over a two-year period.

UT also has a centre for innovation and technology, where elective courses are offered to students, although this centre does not currently have much space available for engineering students. For engineering students, it is mandatory to take courses that contain some education in entrepreneurship and innovation, such as the courses called GMI and GMSI. For these courses, UT hires teachers with industry experience.

KU is pressured to develop capstone design courses for all engineering students, and these courses are therefore developed within the School of Engineering. No clear strategy for building up the competence among faculty was described by the informants, but the teachers of capstone design courses are now predominantly teachers with industry experience. KU has a centre for innovation, which is used to pursue entrepreneurial activities. The Business School offers elective courses for all students in the area of innovation and entrepreneurship. It has been difficult for engineering students to enter these courses (because the Business School has to prioritise its own students), so the Business School now offers two courses devoted exclusively to engineering students.

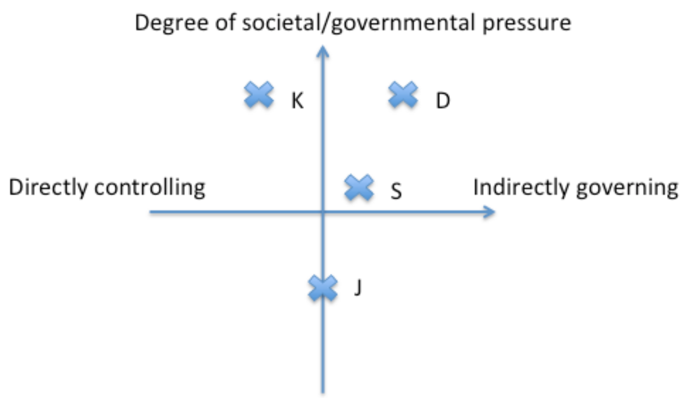
As in Denmark, at Sweden's KTH, no legislation makes it mandatory to teach entrepreneurship in engineering-education programmes. But the external forces have led to the development of a master's programme in entrepreneurship and innovation. There is also a link to the Stockholm School of Entrepreneurship, where engineering students can take elective courses in this field. Enthusiastic professors, with support from management, have also initiated projects like the Open Lab, where students work in interdisciplinary teams on real-life problems, or the Global Development Hub, where teachers and students work on problems in developing countries together with students and faculty in the relevant countries. In those projects, there are elements of faculty training with designed courses for faculty on how to teach entrepreneurship.

4. DISCUSSION AND CONCLUSION

This study shows that the driving forces for developing entrepreneurship education vary across the four countries. It is also plausible that these differences have led to the different approaches/strategies taken by each EEI.

An important area of difference is how much pressure is put on the universities from the surrounding society and how this pressure is expressed. Figure 2 shows an estimated degree of pressure directly controlling the university and, on the other hand, if they are more indirectly governing by promoting activities The figure shows that in the development of entrepreneurship education, both Korea and Denmark experience strong pressure from society as well as relatively strong support from government and other actors. Korea stands out as the country where there is also direct pressure on engineering education; the government partially controls the presence of entrepreneurship education in the form of capstone design courses. In Sweden and Japan, social pressure seems to be somewhat weaker than in the other two countries, although there are similar activities supported by governments and authorities to a lesser extent.

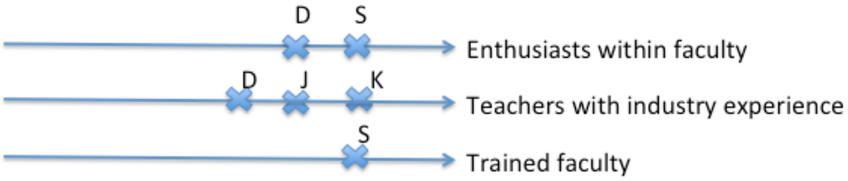
Figure 2. External pressure to develop entrepreneurship education.
DK = Denmark, J = Japan, K = South Korea, S = Sweden



We argue that the different approaches taken at the different EEIs are related to what kind of working force is or has been involved in the processes of developing entrepreneurship education (see Figure 3). In the two Nordic countries, the development of entrepreneurship education in the universities has relied very much on enthusiastic faculty members who believe in its importance. This might be due to the relatively long history of having entrepreneurial skills and enterprise on the educational agenda.

In the countries where we find strong pressure from society, we also see a high degree of involvement from people in industry. This is also true for Japan. Sweden stands out as the country that has come the furthest in the planning of developing the faculty in charge, even though this does not seem to be a well-defined strategic plan.

Figure 3. Persons involved in the work of entrepreneurship education. D = Denmark, J = Japan, K = South Korea, S = Sweden



In conclusion, this study indicates that two of the universities, AU and KU, are working harder than the other two to ready themselves and their students for important changes in how engineers work—changes that will necessitate a broader competence in entrepreneurial skills and enterprise. The other two EEIs, KTH and UT, seem to be aware of the important changes on the horizon, but they are not making proactive attempts to change engineering education accordingly.

These differences may depend partly on the country in which the EEI operates, but the differences may also depend on the characteristics of the EEI itself. Potentially crucial factors are the size of the university, its ranking, and whether it is a private or state university. We will investigate these factors more deeply in our next study.

ABSTRACT

Most universities pursue efforts to provide students with the best skills to tackle the employment market by offering subjects that fulfill market needs**.** By doing so, young engineers will find on the job site a reduction on its learning curve when confronted with similar subjects or even tools. Project management tools are increasingly used in the IT Market but unfortunately, are not widely taught or even applied in the academic context. In order to encourage the teaching of such tools and by having in mind the sustainability of engineering education, we have done a survey on well referenced free project management tools that have the capability to follow some of the PMBOK practices. In this context, we tested and compared the following project management tools: Bitrix24, Zoho, and Wrike.

Conference Key Areas: Sustainability and Engineering Education, University-Business Cooperation and Engineering Skills.
Keywords: Project Management, Free Tools, PMBOK

1 INTRODUCTION

The use of collaborative tools, such as project management tools, have shown greater success in software delivery due to the proper planning that project management tools offer. In a time where only 16,2% of software are successfully delivered on time and on budget, the Standish Group [1], a research advisory organization that focuses on software project performance by discovering why projects fail and how they can better succeed, states that one of the top 4 project success factors is the proper planning.

[1] Corresponding Author : J. S. Pereira, a20105033@alunos.isec.pt
[2] Corresponding Author: J. Bernardino, jorge@isec.pt

IPM Global, a Project Management software development company integrated with Microsoft, SAP and Sage managed by directors working in this field for over 20 years advertises that the use of automated project management tools not only reduces project risks but also enables several other advantages like the centralization of project documentation and the standardization of processes [2]. Allured by the benefits of project management tools, IT companies have been increasingly using project management tools to support project management and to track software development.

These project management tools are used by all project´s stakeholders including software developers - one of the most likely jobs for young computer science engineers – to report their work. Therefore, disclosing project management tools that might be used by students´ future employers it is promoting the teaching of actual professional practices in computer science engineering and better prepare computer science engineers for the competitive IT market [3]. By doing so, young engineers will find on the job site a reduction on its learning curve when confronted with similar project management tools, and consequently, its higher education will be certainly well perceived by the employers.

Even though project management tools are used by all project´s stakeholders. Its principal administrator is the project manager who can follow diverse management practices like the project management body of knowledge guide PMBOK [4]. This guide is a worldwide de facto standard in the project management field that gathers a sum of good practices within the profession of project management.

Nowadays, there is a varied choice of project management tools. Thus, choosing the right project management tool to teach can be overwhelming. In this context, we are interested in the evaluation of free project management tools - most universities have limited budgets - with the capability to follow some of the PMBOK practices – most likely used by IT Companies. Furthermore, we have focused on proprietary tools that have a free version with an unlimited time of use, to enable students to learn and use it at the university. The drawback of these free proprietary versions is the limitation of features compared to the complete paid version. On the other hand, the significant reduction of the young engineers´ learning curve on the job site, when confronted with the same tool, is the biggest counterpart and advantage - basic features are displayed in the same manner than the paid version.

Therefore, this paper aims to guide Professor´s choice by presenting our evaluation of the following free project management tools: Zoho [5], Bitrix24 [6] and Wrike [7]. These tools were selected due to the good feedback that the IT consultant Capterra gave in 2017 [8], as well as its wider coverage on PMBOK´s suggested features. By Capterra´s ranking, Bitrix24 stands at the 1st position, Wrike at the 5th and Zoho at the 8th position but the PMBOK guidelines were not considered for the ranking of these tools which leads us to a deeper assessment.

The remainder of this paper is structured as follows. In section 2, project management tools are described regarding its principal features and its strengths and weaknesses are exposed. In section 3, the methodology used to test the tools is disclosed. In section 4, the tool's comparison is presented and the best project management tool to teach is suggested. In section 5, related work is briefly presented and finally, in section 6, conclusions and future work are exposed.

2 PROJECT MANAGEMENT TOOLS

In this section, we describe the selected tools: Zoho [5], Bitrix24 [6] and Wrike [7]. In order to portray these tools, we describe its principal features as well as its main strengths and weaknesses.

2.1 Zoho

Zoho [5] is actually used by 15 million users worldwide and has a set of free features that can be considered, among others tools in the market, pretty complete. Its main free features are user assignment, user profile configuration, file upload – up to 10MB - and generation of notifications. Notifications can be sent to the user´s e-mail or to the online platform wall, which enables to at a glance see all recent activities.

In spite of not having a tracking of the worker´s time spent on its task neither a CRM, all basic features from the PMBOK guide exists: tracking a project with a Gantt chart, managing tasks and subtasks with dependencies and priorities, graphically visualize the tasks and the whole project achievements, and provide the communication between stakeholders.

During our tools´ evaluation, we have seen that Zoho presented a better dashboard than Bitrix24 and Wrike. In fact, in an appealing graphic form, Zoho displays the percentage of tasks, subtasks and project lifecycle phases that are completed, as well as the percentage of completion of the overall project.

In *Fig. 1* we present the interface of the Zoho tool. At the top center of the print screen, we can see the name of the project that we have created to test this tool. At below left we can see the menu of the tool and at below right a part of the Zoho dashboard where in this case the number of open, closed and total of tasks of a milestone is seen graphically with a donut chart and the task completion percentage with a line chart.

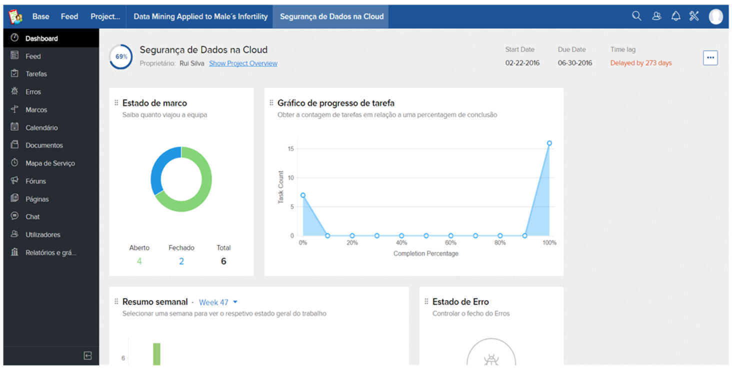

Fig. 1. Zoho Dashboard

The major advantages of this tool are:

The existence of a dashboard; The unlimited number of users that can be assigned; The error feature – project errors can be registered; The unlimited time of use.

Its major weaknesses are:

The number of projects that can be managed - in the free version only 1 to 5 project; The unavailability to track the worker's work time - the tool does not have a timer to track the labor-time.

2.2 Bitrix24

The Bitrix24 [6] is one of the most complete free project management tools seen on market and is also well classified by the IT consultant Capterra [8].

It covers most of the features that we have analyzed but it does not have the capability to graphically visualize the tasks or the whole project achievement, nor set prioritization on the tasks to be done.

Among the tools presented in this paper, it is the only one which has a timer to track the labor-time. This is useful to monitor and control the time taken to execute project´s tasks and consequently, manage the labor-time.

The Bitrix24 interface is shown in *Fig. 2* with the time tracking active: at left, Bitrix24 menu is shown, at center, task´s time management is seen and in the top menu, at right of the presented hours, the timer is shown.

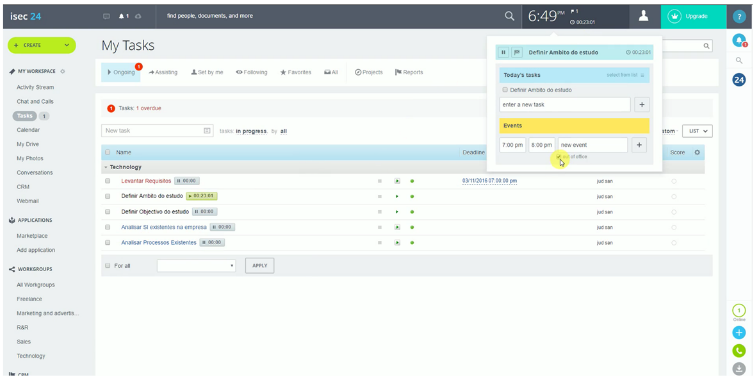

Fig. 2. Bitrix24 Time Tracking

The principal advantages of its use are:

Appealing interface; Wide set of features; Having a Customer Relationship Management feature (CRM) – this system allows to manage business relationships; Having a labor-time tracking and an unlimited time of use.

Its principal weaknesses are:

It is not possible to set task´s prioritization and it does not have a dashboard to in a glance track the progress of the project.

2.3 Wrike

The project management tool Wrike [7] has been named a 2014 “Cool Vendor” in social software and collaboration by the IT Consultant Gartner, and many renowned companies, like PayPal and HTC, relies on it.

One of our interests to analyze this project management tool was its possibility to integrate with the Windows, the most common operating system used by IT companies, through the Microsoft Office 365 version [9]. Therefore, it is a project management tool that goes with the aiming of this paper – the disclosure of project management tools that are more likely professionally used by IT companies to promote the teaching of actual professional practices.

Nevertheless, during our tool´s evaluation and comparison, we have seen that Wrike covers fewer features in its free version than Zoho and Bitrix24. Furthermore, the most important ones, like the Gantt Chart, is only available for 30 days. Therefore, we can say that it is a limited platform in its free version. However, its simplicity and good capacity on performing are better than the other two in the sense that all covered features were highly scored during our experiment.

In *Fig. 3* the Wrike interface can be seen: at left we have the Wrike menu and at right, its Gantt chart where dependencies are seen between the inserted tasks.

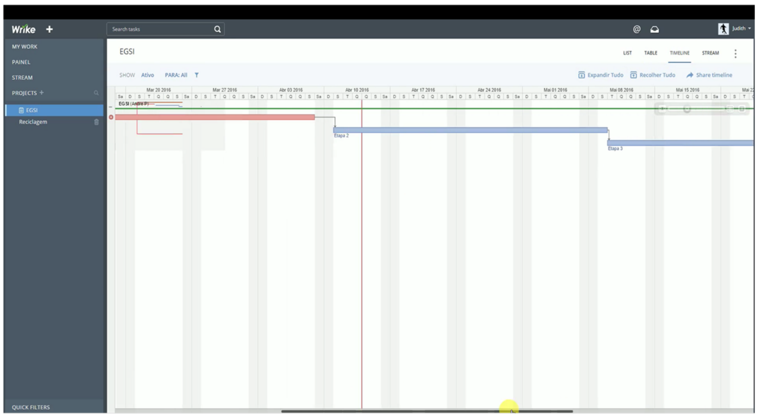

Fig. 3. Wrike Gantt Chart

The main advantages of the Wrike tool are:

The functional stability in its features, in part due to its simplicity; The unlimited dependencies that can be created between inserted tasks; The ease of use.

Its main weaknesses are:

Feature´s limitation; The 30 days' time limit for the use of the Gantt Chart feature.

3 TOOL TESTING METHODOLOGY

By considering most online free project management tools, a set of common features was identified. To those features, we added some of the PMBOK basic methods, specifically the ones suggested for project time management. Afterward, we have tested each tool regarding the existence, the utility and the ease of use of each selected feature, and have evaluated it by assigning a score from 1 to 5 to each feature. Finally, we have added up the features scores and the best tool was identified. This testing methodology was inspired by the Project Management tool selecting criteria proposed by the author Lornel Rivas et al. for small to medium enterprises [10].

For the scoring of the assessed features we have defined the following criteria:
0 = The tool does not have the feature; **1** = The tool has the feature, but it is not useful and its use is difficult; **2** = The tool has the feature, but it is not useful in spite of its ease of use; **3** = The tool has the feature, it is useful but it is difficult to use it, not well conceived or does not work properly; **4** = The tool has the feature, it is useful and easy to use; **5** = The tool has the feature, it is useful and intuitive.

The selected features that we have used to assess the free version of Zoho [5], Bitrix24 [6] and Wrike [7] were:
Add users - possibility to add at least 3 users to the project management tool.
User Profile - possibility to configure user´s different accesses to the online platform.
Task Timer - tracking of the worker´s time spent on its tasks (employees can start in the platform a timer function by the time a task is started).
Chat - possibility to have written online meetings or discussions with the added users.
Upload up to 10 MB - capability to store documents, at least up to a total of 10 MB size, on the online platform to share among added users.
Manage 12 tasks - capability to manage at least 12 tasks that have a duration bigger that one day long.
Manage 4 subtasks - capability to manage at least 4 subtasks.
Task dependency - dependency between tasks and subtasks to establish an execution order to ensure that team members follow the project sequence that was initially planned.

% of task´s conclusion - capability to track the achievement of the tasks by graphically consulting the percentage of its conclusion.
Task prioritization - capability to define tasks´ priority and track it graphically.
CRM - Customer Relationship Management feature that provides the possibility to record, manage and analyze customer interactions and throughput of the customer lifecycle [11].
% of project´s conclusion - capability to track the achievement of the whole project.
Gantt chart - capability to graphically manage the tasks of the project. A Gantt chart represents schedule information where activities are listed on the vertical axis, dates are shown on the horizontal axis, and activity durations are shown as horizontal bars placed according to start and finish dates [4].
Notifications - informs when a task is assigned or overdue by email and/or by adding a post on the online tool wall.

4 TOOLS COMPARISION

By following the tool testing methodology presented in section 3 we have assessed the Zoho [5], Bitrix24 [6] and Wrike [7] Project Management tool and built a comparative analysis that Table 1 depicts.

Table 1. Project Management Tools´ Comparison

Features	Tools		
	Zoho	**Bitrix24**	**Wrike**
Add users	5	5	5
User Profile	5	3	5
Task Timer	0	5	0
Chat	5	5	5
Upload up to 10 MB	3	5	5
Manage 12 tasks	4	5	5
Manage 4 subtasks	3	5	5
Task dependency	5	3	5
% of task´s conclusion	4	0	0
Task prioritization	5	0	0
CRM	0	5	0
% of project´s conclusion	5	0	0
Gantt chat	5	5	2
Notifications	5	5	5
TOTAL	**54**	**51**	**42**

The focus of this paper is to assess free project management tools; thus, the selected features were analyzed and tested regarding its capabilities to perform freely. It is important to say that these selected tools are basically proprietary platforms, which means that are monthly paid, but all of them have a free version, with less functionalities than the paid one that is worth to analyze and consider because of its unlimited time of use. Its limitation is the working context in which they can perform.

During the assessment of the selected tools we have identified the following limitations for each tool:
Zoho - Only works for 1 to 5 projects depending on the number of users added - for every person assigned to the platform one project is added, up to 5 projects. Which means that all tasks can only be related to 1 to 5 projects regardless the number of

users assigned. It can integrate with Google Drive or Dropbox so the 10MB file storage limitation seen in the free version is not an issue, in our point of view.
Bitrix24 - Works with up to 12 users and 5 tasks dependencies. Other than that, its free version is very interesting: it has a CRM and it provides a good user experience given by its appealing interface. Its biggest drawback is its impossibility to define unlimited task dependencies. Furthermore, its users´ profile configuration is very limited.
Wrike - Works with up to 5 users, independently the number of task dependencies recorded or projects mounted. The major drawback is the lack of features, even after migrating to the paid version, comparing to Bitrix24, or even Zoho. The other important drawback of this tool is the 30 days time limit for the use of the Gantt Chart feature, which was the reason for the 2 score given.

By considering the features scores presented in Table 2, Zoho finished with 54 points, Bitrix24 with 51 points and Wrike with 42 points. By weighting them up with them working limitation and user experience, Zoho was identified as the best tool to teach among the ones tested. Zoho election was not only based on its higher score, but also on its capability to better track the scheduled work through the tasks prioritization and project follow up that this tool provides.

5 RELATED WORK

There are actually various published papers in the field of project management tools that can be classified in one of the following types:

- Disclosure of Project Management Tools – popular [12][13], open source or proprietary ones [14].
- Exhibition of open source tools capability analyses vs. proprietary ones [15] [14].
- Presentation of tool´s selection models – [16], AHP model [17] or specified to small and medium enterprises (SMEs) [10].
- Importance of use [18] [19].

This paper falls into the disclosure of project management tools but in the area of studying proprietary project management tools that have a free version that follows some of the techniques suggested by the PMBOK standard. From the best of our knowledge, no other paper approached this topic.

6 CONCLUSIONS AND FUTURE WORK

This paper enabled the identification of the project management tool Zoho, among the Bitrix24 and the Wrike solution, as a suitable tool to teach future computer science engineers. Its free version and wider coverage in features that support PMBOK techniques makes it suitable for universities with budget limitations and for future computer science engineers that aim to thrive in renowned IT companies since they usually follow the PMBOK management techniques. Thus, disclosing the selected project management tools was promoting the teaching of actual professional practices and better prepare students to the competitive IT market.

The selected tools´ evaluation was only made upon its free version, the eventual gap between free and paid versions, regarding features availability, can be bigger in one tool than in another. Thus, the selection of a project management tool with the only purpose of reducing students´ learning curve at the job site, could eventually lead to the identification of another solution. However, we have found, during our testing period, that Zoho offered a bigger functional feature stability than Bitrix24, which justifies the minimal score that separates one tool from the other. As future work, we intend to evaluate the complete paid version of the selected project management tools.

ABSTRACT

The development of Ethics depends on the development of Values, which are shared by a given group and aids people to decide in many situations in compliance with the preferences of the same group. The Ethics in Engineering Education can, in the same way, establish the Values that need to be taught and shared by the Engineering Community. As soon as the society identifies and accept those Values, the Engineers would benefit from a higher evaluation in the society assessment. But Engineering education is suffering from the weakening of its Values motivated by private interest. Currently, the big engineering companies want to reduce the Engineer to a catalogue selling employer. In this paper, we offer the perspective of the relationship between the Engineers and their local communities.

Conference Key Areas: Ethics in Engineering Education, Engineering Skills, Continuing Engineering Education and Lifelong Learning.
Keywords: Engineering Education, Ethics.

1 INTRODUCTION

The education of the new generations of Engineers is no longer a compromise between the society and the University. In the past, the society knew exactly what to expect from few branches of professions. The physicians, the lawyers and the engineers were respected by their behaviours in the applications of their specialized knowledge and skills to solve the problems of the society. Therefore, the notion of Utility was clear and the professionals were praised by this.

Some people may argue that the Professional Values of the Engineers are no longer recognized, because of having much more branches of professions and many

[1] Corresponding Author : R. Q. A. Fernandes, ricardo.fernandes@eb.mil.br

specializations of Engineering. But the impact of having many different tags for the Engineers is internal: the perception of common pertinence is weakened, because the Engineers from different branches do not recognize each other. By this way, to stablish Ethics for the Engineers became much more difficult, but it is not the cause for losing the Values that were stablish in the past.

The downfall of the Ethics in Engineering is much related to the fact that the Engineers may act in different sides of the same issue motivated by the different intentions of their contractors. We may have a Civil Engineer of a Building Company against the interests of a Civil Engineer of the Supervision of Constructions of some Government. As the notions of regulation, contract and payment became much more important, the Ethics in Engineering no longer plays any role in Engineering Projects.

If we want to present to the society that the Engineers have a Code of Conduct, we need to convince the Engineers that the success in the carrier is not a matter of the consumption power they may acquire, but the solutions and well-being they provide to the society, which is the main responsible for the Education they received.

In this paper we analyse the present lack of Values in the Engineering Education and draw the attention to the fact that Engineers must become aware of the ethical and epistemic values embedded in all components of their work. It is also necessary warning the Engineering Schools to avoid the fast exposure of its own students to the interests of the Big Companies. One of the solutions is the inclusion of Ethics subject and Codes of Conduct in all the Engineering courses.

The rest of this paper is structured as follows. In section 2 it is analysed the present lack of Values in the Engineering Education. Section 3 presents the interference of the big companies in the education of the engineers and the corresponding result in their professional carriers. In section 4 we present the Codes of Conduct effort many Engineering Associations conduct as a reaction to sustain Engineering Ethics. Finally, section 6 presents the conclusions and some future work.

2 LACK OF VALUES

In the past, the most prominent experience on professional Values were the “Guild” [1]. They were constituted to organize the labour, the quality and the prices of a given activity in a particular city. The “Guild” respected each other and did not compete. Internally, the members needed to obey many rules to avoid competition, to assure quality and to support the elderly. The professional Values were explicit and the notion of Justice was clear for the society.

According to Tuana [2] Values serve as a guide to action and knowledge. They are relevant to all aspects of scientific and engineering practice, including discovery, analysis, and application. She argues that ethics education should be used in science, technology, engineering, and mathematics (STEM) fields and propose the following main groups of values:

- *Ethical values*: the good of society, equity, sustainability;
- *Aesthetic values*: simplicity, elegance, complexity;
- *Epistemic values*: predictive power, reliability, coherence, scope.

Epistemic and ethical value decisions have important social implications. This fact is reflected in the National Science Foundation broader impacts criterion and its view of the role and purpose of ethics education: “Ethics education is particularly critical to the science and engineering community as it faces an increasingly competitive funding environment; rising collaboration with international colleagues who may follow different guidelines; and growing recognition of the relevance of science and engineering to social, economic, and ethical issues of wide public and political interest." [3].

Nowadays, according to Chomsky [4], we live in a time where people don't think they are able to organize themselves. On the other hand, the media push people to believe the Moral Values need to fit into the constraints of the Individualism. This way, Engineers are free to compete with each other to maximize their profits and to offer lower quality for the solutions the society demands.

In this sense, the labour relationships tend to a single value: the price. But the price is the common agreement between the parts in a negotiation. For this reason, the Engineers are mostly like to worry about their propaganda, not about the quality they offer.

In this sense, according to Bauman [5], the person is the product to sell. And the Engineering title works more as a propaganda item in the curriculum vitæ in the market. We only need to observe the number of Engineers in the Financial institutions to confirm that assertion. Engineers are not always aware of relevant values and ethics education should be designed to promote values identification and analysis.

3 BIG COMPANIES

The dream of the pharmaceutical industry is to transform the physician into a drug vendor. The notion of the cure has shift from a body natural process into a drug manipulation recipe. To achieve this, the pharmaceutical industry need to change the physician formation, the legislation and to make people believe the cure is not in their hands.

In the same way, the dream of the Big Companies is to have highly educated vendors, which are able to convince the local market that the only solution is to buy from its product catalogue.

As the Big Engineering Companies have money to pay more for internships and opportunities to better jobs, the Engineering students starting competing with each other. In the end, the better students are selected to earn higher incomes.

In the process, the student starts to believe in the propaganda of the big companies and in the rules of the market as the only truth behind the scenes: the competition will define their success.

The students have little access to the idea that they can help their own local communities. Those kind of problems, are left to local government only. On the other hand, the local community have little dialogue with the Engineering Faculties to present their problems. Without high internship earning, is hard to find any Engineer student.

After being convinced that about the market rules, the Engineer student, in the middle of its own formation start deciding about the disciplines to follow. At this point, the interest for high-tech products the big companies sell drives the Engineer students out to basic scientific foundations of the Engineering. They tend to follow the propaganda of the dominating Big Engineering Companies. If The Big Companies say that the future is the Storage Technology, then the students are mostly likely to search and demand disciplines related to it. In this situation, after a while, when the Storage Technology becomes commodity, the graduated Engineer will have hard times to change his/her education.

We may see, for example, in the Cisco Engineer Incubator Program in Poland, the interest of a Big IT Company on the education of young Engineers (see Figure 1). The final result of this program is to put the mind set of Cisco in the young Engineers head. The characteristics of the program is given below [6]:

Figure 1: Big Company interest on the education

- ***What is Cisco Engineer Incubator?***

  Special educational program designed by Cisco engineers to support young, talented students and graduates interested in networking technologies and starting the career in IT.

- ***Who is it for?***

  Engineering students (preferably on their last year of studies), with CCNA (Cisco Certified Network Associate) -level knowledge of networking technologies, who see themselves as professionals in IT industry in the future.

- ***How does it work?***

  Free CCNP (Cisco Certified Network Professional) course delivered through technical seminars and webinars between October and May, with regular office visits and meetings with our engineers and managers.

- ***How do I join?***

  We will kick-off the recruitment for the Fifth Edition of the Incubator Program (2017 – 2018) in Spring 2017. Please monitor this webpage for the updates on the application process and the schedule of our university events in Poland.

The notion that the Engineering work may serve to the local community and the society as a hole is weakened. Sooner as acceptable, the Engineer start thinking that his/her work may only serve to a given company, specially the Big ones. We presume Poland need Engineers to develop the country, not only to serve a specific Company for market and profit purposes.

In the end the Engineer has more short term knowledge, as the technologies evolve, which leave them in a dependency cycle on the product catalogues of a given company. They are no longer able to create new solutions. They are only able to prescribe short term solutions the big engineering companies sell.

This intentional choice is not well observed nor controlled by the Engineering Schools. The students are not prepared to recycle their engineering knowledge on top of a solid scientific foundation. The Engineer is left alone on the market with a technology mind set which is condemned to be obsolete.

In this way, the Engineer start depending more and more on the market knowledge: finance, administration, commercial skill need to be developed as fast as possible to be able to survive. The sense of pertinence to the engineering professionals is weakened this way.

The result of all this process is the loss of creativity and social relevance of the Engineer work. The Engineer mental process becomes more and more tight to the available technology culture, including the companies catalogues and the corresponding names and brands. Many of those brands are accepted as a common word in the Engineer vocabulary and are used as buzzwords.

The Engineer then is converted into a complete vendor. The Engineer can only see the society problems as an opportunity to apply all of his/her knowledge: the buzzword of big companies. The Engineer is no longer able to comprehend the society problems first, in a scientific way. He/She is only trained to search in the available catalogues, the possibility of a solution.

On the other hand, this loss of creativity and competitiveness for the local engineers represent a gain for the big companies. They have highly educated vendors with Engineer titles, which act only in the benefit of a given company, not in the benefit of the society. This is an opportunity to broaden its local market dominance as the local Engineers vendors ease the selling communication to the local consumers.

Another interesting aspect of this loss of creativity is the reduced capability of local competition. The local solutions might be a barrier for the big company dominance. But the local engineers are make to believe that there is no solution, but to buy a high-tech product made by better engineers of the big company. And the dominance is reinforced.

One of possible solutions is the use of open source software, free of charge that reduce costs and enhance engineering education with these new open source technologies [7]. With open source software, students have the freedom to put their creativity in action. It is also possible to test and modify the software, simulating real enterprise environments, which improves student's skills [8].

4 CODE OF ETHICS

Nowadays there are many efforts to establish Codes of Conduct among many Engineering Associations, for example: Association for Computing Machinery (ACM), Institute of Electrical and Electronics Engineering (IEEE), National Society of Professional Engineers (NSPE), Engineers Australia and American Society of Mechanical Engineers (ASME).

One of first one's is the American Society of Civil Engineers - ASCE Code of Ethics, which is the model for professional conduct for ASCE members that is first adopted in 1914. The Code of Ethics was most recently updated on July 23, 2006. Pursuant to the Society's Bylaws, it is the duty of every ASCE member to report promptly to the Committee on Professional Conduct any observed violation of the Code of Ethics. In April 1975, the ASCE Board of Direction adopted the fundamental principles of the Code of Ethics of Engineers as accepted by the Accreditation Board for Engineering and Technology, Inc. (ABET) [9]. In October 2009, the ASCE Board of Direction adopted the following definition of Sustainable Development: "Sustainable Development is the process of applying natural, human, and economic resources to enhance the safety, welfare, and quality of life for all of the society while maintaining the availability of the remaining natural resources."

Another example of Code of Ethics is the ACM Code that provides guidance to ACM members about committing to ethical professional conduct. The Code identifies fundamental considerations for contributing to societal and human well-being. Every ACM member who renews a membership agrees to adhere to this code, a code that was written a quarter of a century ago.

The current version of the Code was approved in 1992. This version of the Code made significant advances over its predecessor. In its role of advancing professionalism and producing a positive impact on society, the ACM replaced the previous primary function of monitoring member behaviour with an emphasis on educating about the principles of ethical behaviour in computing and providing guidance in ethical decision making. Over the years, the Code was used as a guide to instruct students entering the profession, as a decision support tool for computing practitioners, as a standard for the public to judge the professionalism of practitioners and as an aid to address legal issues and ethical tensions. In the last few years, many questions arise related to artificial intelligence, machine learning, and robotics.

In the 25 years since the drafting of the 1992 Code began, there have been two significant, interconnected, and broad kinds of changes: 1) amazing changes in computing technology, and 2) important changes in how deeply that technology is integrated into social structures and into people's daily lives. The technical changes are substantial. The number of people impacted and the intensity of that impact have been astonishing.

In 1992 the number of people using and controlling computers seemed limited. Computers were typically in a fixed location, and were just beginning to connect via the Internet. Computers were used to print bills, to control some highly specified processes, and to guide military devices. They managed and recorded financial information, controlled some processes on our automobiles, and controlled micro-waves in the air and in our kitchens. It made sense for most scholars in computing to have a narrow focus on the analysis of algorithms and a study of the resources needed to execute them. Now computing is ubiquitous— controlling our transportation and communication, and facilitating many human interactions. Computing today is in our bodies—prosthetics, pace- makers, and insulin pumps. Computing is also integral to the ways in which societies wage war. Computers impact all areas of our lives and many life- preserving functions are relegated to a piece of computer guided machinery. Many of the newest impacts of computing are invisible. Computers make decisions about who is audited, who gets a heart transplant, and who gets targeted by dangerous devices, be they cars or missiles. The changes in technology and the kinds and number of impacted stakeholders are changing society in fundamental ways.

Recently, the ACM Code of Ethics and Professional Conduct: Draft 1 was developed by The Code 2018 Task Force and the preamble is as follows [10]:

> *"Commitment to ethical conduct is expected of every ACM member. The ACM Code of Ethics and Professional Conduct ("the Code") identifies the elements of such a commitment.*
>
> *This Code includes 24 imperatives formulated as statements of responsibility. The Code is designed to apply to practicing and aspiring computing professionals. Section 1 outlines fundamental ethical considerations. Section 2 addresses additional, more specific considerations of professional conduct. Section 3 pertains more specifically to individuals who have a leadership role, whether in the workplace or in a volunteer professional capacity. Principles involving compliance with this Code are given in Section 4.*
>
> *Each imperative is supplemented by guidelines, which provide explanations to assist members in understanding and applying the imperative. The Code is intended to serve as a basis for ethical decision making in the conduct of professional work. Secondarily, it may serve as a basis for judging the merit of a formal complaint pertaining to a violation of professional ethical standards.*
>
> *The Code as a whole is concerned with how fundamental ethical imperatives apply to one's conduct as a computing professional. The imperatives are expressed in a general form to emphasize that ethical principles which apply to computing professionals are derived from broadly accepted ethical principles.*

> *The Code is not an algorithm for solving ethical dilemmas. Words and phrases in a code of ethics are subject to varying interpretations, and a particular imperative may conflict with other imperatives in specific situations. Questions related to these kinds of conflicts can best be answered by thoughtful consideration of the imperatives and fundamental ethical principles, understanding that the public good is a primary consideration".*

The Engineering Associations offer a high value contribution to the establishment of Engineering Ethics. But those codes of conduct are limited to the scope of a given Association. It means that they do not have the same law enforcement power as the Guild in the past. If a professional of a Guild do not followed one of the rules of the Guild, this professional is left out of the city.

On the other hand, there are many different approaches related to the different codes of conduct efforts. In this sense, the same problem of having many Engineering branches arises: the notion of pertinence is restricted to a given Association. And how can one Engineer from one Engineering Association can trust other Engineer from a different Engineering Association as they have different codes of conduct? In this way, we tend to favour the Engineers relations of the same Association. There is little explicit mention on those codes of conduct about the mutual respect among different Associations.

5 CONCLUSIONS AND FUTURE WORK

Engineers must become more aware of the ethical and epistemic values embedded in all components of their work as well as their significance and role in research and practice through training for values transparency and coupled ethical-epistemic analysis skills.

The Engineering Schools should avoid the fast exposure of its own students to the interests of the Big Companies. They need to understand the value of the Engineer. The society need to develop solutions for its own demands. The Engineer is the professional to offer them. The Big Companies want to maintain its own Engineering skills, reducing the local competition for solutions. The Engineering vendors maximize their profits.

The Codes of Conduct efforts represent the hope in future to establish the Engineering Ethics. But they need to grow outside the Engineering Associations limits to become an essential part of the Engineering education.

As future work we propose a study about the relationship between education and the demands of the local communities. We believe that this relationship is stronger whenever a community believes it is own responsibility to solve its own problems.

ABSTRACT

The engineers need not only good knowledge of their special technical field but also e.g. social, analytical thinking, problem solving and language skills. Especially knowing how to learn and adopt new and how to combine their own knowledge with other specialists is important. All these require consideration when reforming the new curricula. This article describes the process of the curriculum development in the Mechanical Engineering Education.

The new curriculum is based on competence and problem-based learning. This new curriculum challenges the teachers to be more like counsellors in the students' learning processes. This new curriculum also motivates the teachers of different subjects to cooperate and teach together with each other. This makes the teachers plan, check, guide and assess the courses together. Competency-based curriculum considers the students more as individuals than as groups and this requires the students to be more active in their learning process.

In the department of Mechanical Engineering, the new curriculum consists of the academic year and semester themes. The academic year themes are *Learning about Work of Mechanical Engineers*, *Engineer's Toolbox*, *Creative Engineers* and *Pre-Engineers*. Every semester has a CDIO-type semester project course and all the other courses support this project course.

Conference Key Areas: Curriculum Development, Sustainability, Skills and Engineering Education
Keywords: Curriculum Development, Competence and Problem Based Learning, Collaborative Teaching

INTRODUCTION

The development of the curriculums is a challenging and time-consuming process. How to anticipate, what kind of competence is needed in the working life in the future? The operational environment is changing so fast that it is hard for the educators to keep up with it. In different education fields, there are permanent topics in engineering education; it is necessary to teach natural sciences and selected subjects of the technical field but also social skills, analytical thinking skills, problem solving skills, language skills are needed in the working life. The students must know how they learn and adopt new and how they can combine their own knowledge with other students.

The new curricula of Lappland University of Applied Sciences are based on competence and problem-based learning. These new curricula challenge the teachers to be more like counsellors, not traditional teachers in the students' learning processes. These new curricula also motivate the teachers of different subjects to cooperate and teach together with each other; every course has to have more than two teachers. Competency-based curriculum considers the students more as individuals than as groups. These new curricula also require the students to be more active in their learning processes and this has to be emphasized and taught to the students.
The engineering education is not the most popular subject to study nowadays. If the students are not committed to the subjects they are studying, or they do not know what kind of work the engineers do, they may not be so motivated to study and they may drop out their studies. The thread of the mechanical engineering competence was in the center when the new curriculum of the Mechanical Engineering Education was reformed. The new curricula will be introduced in the fall 2017.

1 GENERAL

Lapland University of Applied Sciences (later LUAS) started at the beginning of 2014. Two different Universities of Applied Sciences (Rovaniemi University of Applied Sciences and Kemi-Tornio University of Applied Sciences) merged and it was necessary to start pedagogical development and combine different practises. One of the important tasks was to reform the curricula of the different degree programmes. The content of the European Bologna Process and the funding model of the Finnish Ministry of Education for the Finnish universities and universities of applied sciences also influenced the curriculum development and reform. The operation environment and working life expect from the future employees that they are able to learn by themselves, together and from each other and they can build new information combining their own knowledge with other specialists. The target of the new curriculum is to confirm a creative and learner-centered culture of learning. Fragmentary courses are integrated into larger modules and students together process the phenomena and problems of the working life.

The aim of the problem-based learning is to increase creativeness and communality in the students learning process. The individual students study as active team members resolving learning problems. The alternative proposition of the solutions expand the students' individual knowledge. The target of organizing the learning is to reduce teacher-centered teaching and increase work-oriented learning. The essential themes are interaction and co-operation between the students, communal learning, the guidance of the learning, invocation of the group dynamics in the learning process and developing evaluation.

The old curricula of the different education programmes are usually separate 3 credit courses including general studies, professional studies and line specific studies but they are rarely connected with each other; only some courses. This may produce some disruption in the students learning process where they do not see the meaning of learning of these different skills and the motivation of performing these courses may not be so high. With the new curriculum, these separate courses vanish or are reduced. In the curriculum of the engineering programmes, e.g. the general studies are connected more tightly to professional studies. The thread of the courses in the whole degree is more clear to the students, which may also enhance the study progress and reduce drop-outs.

Project-based learning is applied in the curricula of different engineering programmes. This new curriculum challenges the teachers to be more like instructors, not traditional teachers in the students' learning processes. The teachers have to learn a new role and instruct the students in their learning process and task. Instead of giving a lecture, the teacher introduces a problem and the students search for information and try to solve the problem. Therefore, information retrieval is essential in the learning process. This new curriculum gives the teachers of different subject the possibility to cooperate and teach together with each other. In this way, the individual teachers really get better overview of the education and have an insight into different subjects. Therefore, the integration between different subjects deepens. Earlier the teachers liked to teach alone so that the doors of the classrooms were closed and every teacher could give best information with his/her own individual expertise. The team teaching is the cornerstone of operations in the competence-based curricula. The team teachers plan, teach and assess the pedagogic learning process together. It is not easy for a teacher to change his/her teaching method to competence and problem-based one and act more like counsellor. In the curriculum process of the LUAS, there were quite many events and education session for the teachers on competence and problem-based learning and team teaching so everybody knew what that means in their own teaching. The students are not familiar with this kind of teaching method and that is why the teachers have to introduce the new curriculum to the students and explain the working method and assessments of the courses. Emphasising a student-centred approach will also speed up studies. In addition, recognition of prior learning will be improved, and work life orientation and teaching of entrepreneurial skills will be increased.

2 PROCESS OF THE CURRICULUM DEVELOPMENT

At the beginning, there were quite many events and education sessions to the teachers on competence and problem-based learning and team teaching in the curriculum process of the LUAS. Some of the events were hold to the entire staff together; some events were hold to the different educations (e.g. engineering education) only. This was a major investment of time and money from the LUAS to improve the teachers' competence of the new curriculum. All of these events also improved mutual work where different teachers of the education shared their expertise.

In every education programme, a teacher was named as a person in charge of the curriculum. These persons (in charge of curriculum) led and coordinated the work of the curriculum development in the education programmes. They had several meetings together regularly and shared each other the current phase of the curriculum development process of different education programmes. New information and practices were rapidly used in the development processes of the curricula. These kinds of activities also increased shared expertise inside the education programmes.

2.1 On the way to the new curriculum of Mechanical Engineering

Bachelor of Engineering studies take four years to complete containing 240 ECTS credits. The structure of the Mechanical Engineer curriculum consists basic and professional studies 180 ECTS (basic studies (50 ECTS) and professional studies (130 ECTS)), elective studies 15 ECTS, practical training 30 ECTS and thesis 15 ECTS.
First, the teachers, students, representatives of the surrounding industry, co-operative companies and other important partners, e.g. research groups, were asked to specify the competences of the mechanical engineers. A lot of time was spent on this work but it was also interesting and rewarding to analyse and anticipate the skills the future mechanical engineers need in the changing working life.

The new curriculum of Mechanical Engineering was created from a “blank slate” and it consists of projects and various study modules reflecting the competences. The names of these projects and study modules are inspiring and modern and try to illustrate better the theme of the academic year to the students. The competence of the Mechanical Engineering is based on the contents of the projects and the aim of the know-how of the study modules. The professional growth of the mechanical engineers proceeds gradually from the first academic year to the last year in every academic year and semester themes.
The learning and/or problem-based project is in the center of every semesters theme. The contents of the different study modules are integrated into the content of the semester project. The competence of the student is based on these semester themes. Figure 1 presents an example of a semester project, and how the study modules support this.

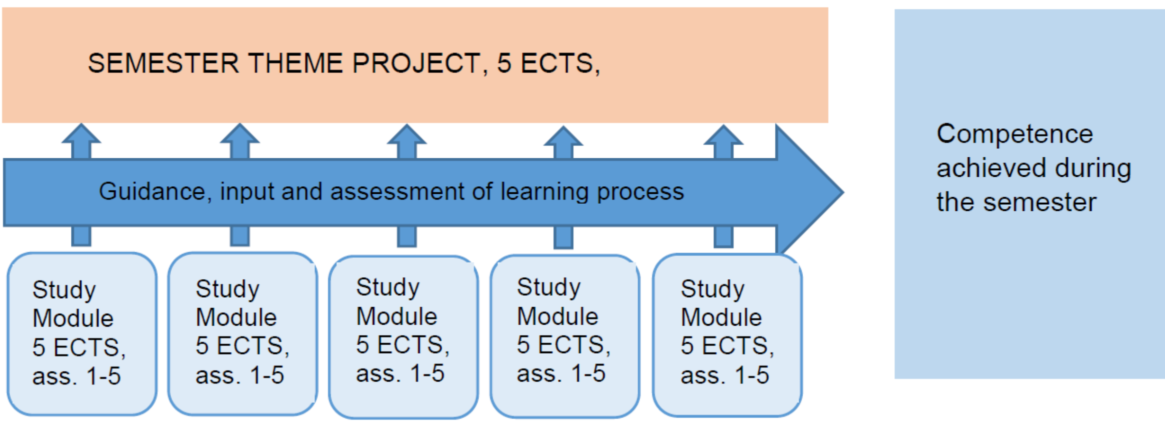

Fig. 1. An example of the semester theme.

In the region of Lapland, there are steel, paper, energy and mining companies and their needs of the future professionals were taken into consideration when determining these alternative professional studies. It is also important that there are possibilities to gain academic competence in the region. The people who live in the region are used to long distances of the services and artic condition. In the Mechanical Engineering education in the new curriculum, there are three different kinds of alternative professional study options and the students choose one of them in the third academic year. These alternative professional studies are: Industrial Professional, Product Development Professional and Mining Professional. All of these alternative professional studies contain semester projects, mandatory courses and optional courses. Figure 2 presents the description of these alternative studies.

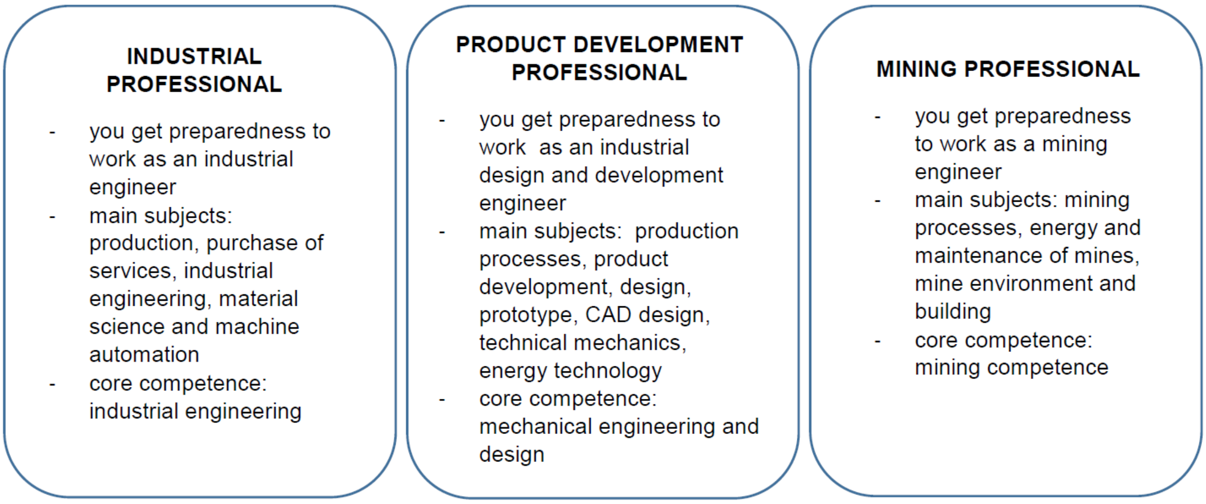

Fig. 2. Alternative studies of the Mechanical Engineering

3 EXPERIENCES OF THE COLLABORATIVE CURRICULUM PLANNING

In the department of Mechanical Engineering, the academic year consists of the semester themes. The academic years have the following themes *Learning about Work of Mechanical Engineers*, *Engineer's Toolbox*, *Creative Engineers* and *Pre-Engineers*. Every semester has a semester project course and all the other courses support this project course. These semester projects are like CDIO projects (Conceive-Design-Implement-Operate). The professional competence is developed by active learning and supervision methods.

The same curriculum is applied in young and in adult education, only some of the vocational subject studies are compensated with practical training. The students in adult education study in the evenings and on Saturdays, and so the number of contact lessons is smaller and this sets its own demands and restrictions in the teaching methods as well as in the curriculum. The students must be self-directive in order to manage their studies along with their work and private lives. The teaching methods can consist of e.g. flipped classroom, simulation, online teaching and independent studies.

Table 1 presents an example of the content of one academic year (first academic year). The first year is critical for the students if they are not motivated and they do not recognise and understand the professional field of the studies. Therefore, they are possible dropouts. In the new curriculum of Mechanical Engineering, there are many studies were the engineering work and working environments are demonstrated with basic and professional studies. In the old curriculum of the Mechanical Engineering, the basic, professional and elective courses were mainly 3 ETCS. The basic courses consisted of maths, physics, language, communication and learning skills. The professional courses consisted of different kinds of sections of Mechanical Engineering.

Table 1. An example of the content of the Academic Year.

1. Academic Year					
Academic Year Theme	Semester Theme	Study Module	Extent	ResponsibleTeacher	Other Teachers
Learning about Work of Mechanical Engineers	On the Way to Becoming an Engineer	**Project**: Familiarization with Arctic Working Environment	5	N.N.	A.A., B.B., C.C.
		Perspective on Work of Engineers	5	N.N.	A.A., B.B., C.C.
		Natural Sciences of Engineers	5	N.N.	D.D.
		Tools and Software of Learning	5	N.N.	E.E.
		The basic of Technical Design	5	N.N.	
		Basics of Industrial Engineering	5	N.N.	F.F.
	Language of Engineers	**Project:** How to Use the Tools of Engineers	5	N.N.	A.A., B.B., C.C.
		Tools of Mathematics and Physics	5	N.N.	G.G.
		Basic of Mechanical Engineering	5	N.N.	A.A., B.B., C.C.
		Manufacturing Processes and Material Science	5	N.N.	
		Basics of Technical Mechanics	5	N.N.	
		Projects and Workshops	5	N.N.	A.A., B.B.

The engineers need not only good knowledge of their special technical field but also e.g. social skills, analytical thinking skills, problem solving skills, language skills. Especially knowing how to learn and adopt new and how to combine their own knowledge with other specialists is important. All these require consideration when drawing up the new curricula. In the process of the curriculum development, a lot of effort was put when considering the themes and names of the semesters. It is necessary that students, mainly young people, understand what they study and what kind of competence they achieve. It is also important that all this is presented in "young people's language". The academic year and semester themes also portray well the idea of Mechanical Engineering studies.

In the first academic year, the field of Mechanical Engineering becomes familiar to the students. They practise basic subjects of the Mechanical Engineering combined to the natural science, language and social skill studies. In the second academic year the basic tools of the Mechanical Engineering become more familiar and the students learn how to apply all the knowledge they have achieved. The students also can work on the projects and they can apply different kinds of problem-based methods. In the third academic year, the students can together solve real working life problems. In the last academic year, the students deepen the Mechanical Engineering competence and at the end of the year they will graduate. The students can work in different kinds of Mechanical Engineering jobs, they manage in different situations and they can be supervisors.

At this phase of the curriculum process, the timetables for the autumn semester are being drawn up. The challenge is to combine the timetable of new curriculum and the old curriculum.

4 SUMMARY

The process have been long and it has taken much time to plan the curriculum together. Drawing up the timetables is challenging because you have to take into consideration the daytime and the adult students, studying according to the new curriculum and the old one.

The assessment of the courses or projects will give new challenges to the teachers, because it is based on continuous learning and the learning process of students and it will be done together with several teachers. On the other hand, the assessment is viewed from different perspectives and this is advantageous to the students. The challenge of the curriculum development processes is that the advantages and disadvantages will be seen when the first students graduate. Time will show.

ABSTRACT

The present world scenario shows that without any doubt there is an increasing recognition that leadership in technological innovation is key to the nation's prosperity and security in a hypercompetitive, global, knowledge-driven economy. Universities must cope with this need and change to reach the levels of required quality education in order to form the professional who will leave university to the work market. The Engineering Education Team of COPEC – Science and Education Research Council has designed this program that is knowledge centered and specially challenging, which integrates classical engineering approaches and real experience in order to achieve a high level of engineers ready to perform as professionals or researchers. The goal is to form the Engineer – a professional that is capable to learn for life and be creative in many ways.

Conference Key Areas: Engineering Skills, Engineering Education Research.

Keywords: learning/teaching tools, best practices, work market, intellectual skills, knowledge-centered.

INTRODUCTION

In general sense, engineers can be defined as problem solvers, creators of ideas and concepts, builders of devices, structures, and systems. They apply their knowledge of science and technology to meet the needs of society, to solve its problems, and to pave the way for its future progress. The intellectual activities of engineering are heavily based on synthesis, design and innovation through the integration of knowledge. However, engineering is more than an intellectual discipline, like physics or chemistry. It is also a vocation characterized by great diversity.

The key to the ability of engineers to develop products, systems and services that are essential to public health, and the economic competitiveness of the nation's business and industry is the knowledge base created by engineering research. The new knowledge, generated through research, drives technological innovation, which is the transformation of knowledge into products, processes, and services, which, in turn, is critical to competitiveness, long-term productivity growth, and the generation of human wealth.

Another aspect is that the current standard engineering education appears neither to provide the full set of skills that engineers are likely to need in the future nor attract the right numbers or types of people to engineering.

Based on these facts the questions that arise are: How can education institutions provide students a strong and valuable knowledge? What key skills and competencies do today's engineers need?

The answer seems to be: if students are taught the skills of learning, then they will continue to learn on their own for the rest of their lives. How is this possible? By the well-walked path of the tried and proven — the classical method of educating engineers. It means sufficient mastery of the basic tools of science and mathematics to address technological problems.

The way this can be achieved is by means of classical education, not as synonym of Christian education, but as an education with solid basis of knowledge in basic sciences and basic sciences of engineering. Students then will finish their course equipped with the right tools and a strong capacity of learning. Classical education then, in this sense, is a life-long process of applying the “tools of learning” - tools that are skills entailed in basic sciences, engineering basic sciences, and specific of engineering, which travels with the student through her/his career as professional or as an academic. In other words, the market seems to be ready for those who obtain a general engineering education and develop adaptable skills, which will serve them while their world continues to evolve [1].

Knowledge is a web, and so, there are no subjects that are unrelated to others. It happens the same with engineering training; the program is a web of knowledge, provided by studies, delivered in a time frame, interconnected and necessary to get the pertinent knowledge and development of skills that will enable them to learn by themselves. This is why students have to see the big picture from the beginning. It is important to show them, in the first week of classes, the whole program, as a big frame and its parts and the details of each part. It is a way to locate them within the program. It is hard, but not impossible and the effort is worth. The knowledge of the entire program has an effect in students who can see the value of solid knowledge in basic sciences as a start point for their formation and the importance of these as valuable tools.

Education is established in cultural economic, individual, philosophical, scientific and social advancement. In other words, education is the mean for developing the mind for the betterment of the individual and society. Advances in science and technology mean that the world will continue to change rapidly, so that the knowledge learned by students in specific careers will have a short lifespan. In contrast, those who achieve a general engineering education will develop adaptive skills, which will serve them while their world evolves. Since people tend to change jobs and occupational fields, several times throughout their lives, it is important to acquire a dynamic ability to absorb information, to adjust to organizational goals, and to navigate through complex work relationships; for this reason, a classical approach seems more useful for today’s work market.

The integrating part of the program comes from internships and practical projects, which are relevant for both: student’s studies and the real work scenario. The internship and the project offer opportunities to take the skills they are developing in the classroom to the real world. So, School provides internships in companies, in the field of student’s choice, during the fourth and filth years of college. They are then, at that time, more prepared to face these challenges [2].

The authors use "classical education" meaning knowledge centered education and refer to "classical method of educating engineers" as the same kind of approach. It refers to the choice of in class classes, with face to face interaction, strong and deep study, mainly in mathematics and physics, as the basis for the quality education that provide the tools that conception and application engineers need.

1. PROBLEM FORMULATION – NEW MARKET DEMANDS

The value of narrow specialization, at a time when engineering practice and engineering systems are becoming large and more complex, and involving components and processes from widely dispersed fields, is questionable. Many educators believe that the most important intellectual problems of our time will not be addressed through disciplinary specialization, but rather through approaches capable of integrating many different areas of knowledge.

This fact, added to competitiveness, made an engineering school, of a private University, decide to invest in a new civil engineering program, instead of opening a new program in another field, since this program is still the most sought course by young people in the region.

In order to overcome the difficulties of the hard competition and external evaluation of programs, the University has hired COPEC – Science and Education Research Team for Engineering Education, which has designed a program, which is knowledge centered and specially challenging. It is a program that integrates classical engineering approaches and real experience, in order to achieve a high level of engineers ready to perform as professionals or researchers. Their goal is to train Engineers able to learn for life and be creative in many ways.

The program has been specially designed, and aims to become the best one, in order to attract more students due to the competition in the region, that despite being a relatively small region, has five other universities offering the same program of civil engineering and faces also the external evaluation process by the Ministry of Education [3].

2. SETTING THE CONTEXT: TIMELESS EDUCATION

The classical/general education (and here as opposed to progressive education) is a type of education that has a history of over 2500 years in the West. It began in ancient Greece, was adopted widespread by the Romans, reduced after the fall of Rome, made a slow, but steady recovery during the Middle Ages, and was again brought to perfection in the Italian Renaissance. The main goal of classical education, in any level, is to form the whole person, in accordance with timeless intrinsic values; it is a very effective way to form free citizens, as opposed to controlled citizens.

The classic view of education states, essentially, that human beings are intelligent beings, which means that human beings want to know things, more specifically to know what things are and how they work. It is primarily focused on knowledge and not student-centered [4].

At University level, the classical/general education demands self-discipline and it produces intelligent curious young professionals, who can think, calculate, analyze, understand, solve problems and follow through on a wide range of perspectives. It is systematic and rigorous; it has goals and a method to reach the goals. It provides future professional the tools to learn and to adapt to the new work environment, as well as to the mutant work market of this millennium.

Looking at History, the classic engineering was responsible for the appearance of weapons, fortifications, roads, bridges, canals, tools, etc. In ancient times, in the eighteenth century, the first engineering schools emerged in France. They are: the École des Ponts et Chaussées (1747), the École de Mines (1783) and the École Polytechnique

(1794), it was the period when Science married Engineering. They all belong to the group of French Schools, that constitute mostly the so-called "generalist" Grandes Écoles, and the leading ones, of these groups, constitute the major part of the French scientific elite education system [5].

In the field of science research, what has been seen is that research work is not based on a top-down command-and-control hierarchy anymore. In this new virtual and complex system, scientists combine and recombine in research teams, based not on academic discipline or institutional affiliation or geographic location, but on the unique requirements of the problems they want to address. It means that researchers do not have to be in the same place of their collaborators, nor have they to be in the same place as the problems they seek to solve. There are international networks, which are more important to individual faculty members, than their departmental or institutional ties, since this network enlarges the possibilities of research and career success [6].

Besides this, the time is coming, when most people will have a number of jobs before middle age and when many jobs have not yet been developed; the question is: how can educational institutions form or train in a manner that may not yet exist? The classical/general education curriculum provides an answer.

3. THE APPROACH: THE CLASSICAL EDUCATION IN CIVIL ENGINEERING

It is estimated that today's college students will have over four jobs before the age of 30, and over ten jobs before they are 40. For core science, research, engineering and technology jobs specifically, around 78% of the net requirement between now and 2023 is made up of replacement demand, leaving 142,000 brand-new core science, research engineering and technology jobs being created. These new jobs are being created in a range of areas, with some sectors becoming much more science-focused over time. It means that there will be new opportunities and changing jobs is a very possible need [7].

In fact, many engineering graduates will work for small high-tech companies or consulting services companies, moving from organization to organization and role to role frequently. To adapt to this new work environment, engineering graduates must accept the personal responsibility for their lifelong learning through acquiring effective self-learning skills.

Perhaps, what is most missing in the current engineering education curriculum, crammed as it is increasingly with demanding technical material, is the opportunity for a truly liberal education, designed to enable young students to develop the deeper intellectual skills necessary to adapt to a world characterized by continuous change. So Classical Education can be a way to enable students for this new work market.

Classical/general education can be defined both: as a curriculum for broadening the mind—one of the hallmarks of an educated person—and as a way to prepare for active participation as a citizen. At present time, there is a sense that classical/general education should focus in the key attributes that employers value as needed by a generally educated person: critical thinking, writing, speaking, arguing, researching, and mathematical reasoning. In addition, to introduce a broad variety of subjects, classical/general education should exercise skills and habits of mind.

After the Second World War, with the cold war, and the run for the moon, education suffered a big change, added by the enlargement of students in University. These changes were necessary, however, due to the challenging and mutant educational environment as well as the global market and the scientific and technologic new achievements it is rather difficult to figure out what kind of engineers training will be necessary. In order to face the new challenges, the classical engineering training is an approach that provides new engineers the right tools to perform and to learn for life [8].

There are two facts that have driven the engineering faculties: first, private universities are struggling to attract good students for their programs, once it guarantees the continuity of the colleges and programs and so the employees. Besides the external evaluation, that programs and colleges have been facing, push them to enhance the quality of the programs that they offer.

Because of these reasons, to attend the necessities of an engineering college of a private university, COPEC's team has chosen to propose the pursuit of a classical/general education approach for the civil engineering program and so form the "Engineer". The engineer who has knowledge and self-taught skills - a professional who can think, calculate, analyze, understand, solve problems and follow through a wide range of perspectives - social, economics and of sustainability among others. It is a way to attract good students to their programs, as it ensures the continuity of colleges and programs.

The proposed program is essentially, what says a famous and very appreciated Chinese Proverb – "Give a man a fish and you feed him for a day. Teach a man to fish and you feed him for a lifetime".

The specific civil engineering program started in 2014 and the enrollment was low, comparing with previous years. However, after three years the results have been very positive taking into account the trend of engineering programs, choices in young generation and the universities competitiveness for students in the region.

4. ENGINEERING EDUCATION – FACING GLOBAL MARKET

Civil engineers must serve in a competent, collaborative and ethical way, working as planners, designers, builders and promoters of the economy and construction as a factor of social promotion. In addition, they are managers of the natural environment and its resources, innovating and integrating ideas and technology in the public, private and academic sectors. They are the managers of risk and uncertainty caused by natural events, accidents and other threats; and also leaders in discussions and decisions that shape environmental policy and public infrastructure.

The proposal of a classic engineering program came as a response to develop a new educational approach with the goal of strengthening a civil engineering course that saw its enrollment declining each year.

The key elements are:

- have a well conceived, coherent, sequential curriculum;
- have all courses with strong and pertinent knowledge;
- adjust other parts of the education system of the program to support the goals of learning;
- provide teachers with a carefully conceived curriculum, filled with challenging texts and materials;
- provide students where they are going and how they are going to get there.

It is necessary to challenge students to acquire the knowledge that they really need to become engineers; a professional capable to do any work and overcome the unpredictable future when it is becoming difficult to anticipate the new professions and opportunities that will be needed [9].

The process is long, implies many changes, including teachers trained for the program and the achievement of the main objective, which is to foster in the students the analytical and verbal skills, creativity and innovation, entrepreneurship, the appreciation of complexity and ambiguity, and leadership, very important for the formation of the engineer of this millennium.

The curriculum has been set and discussed with a set of professors, specialists in their fields of expertise, and in accordance with the Law of the Ministry of Education, the organization that regulates and accredits University Schools Programs.

The curriculum is organized in order to provide students with basic sciences courses, taught during the first two years; followed by basic sciences courses of engineering deployed during the second and third years and the specific courses of engineering, in this case, civil engineering, with emphasis in concrete constructions and eco building construction (following the trend of sustainable buildings – energy efficiency and use of low emission of Co2 materials) [10].

The figure below shows a block of different courses that were added and that have been taught in a period that has been named as Pre – Program, which happens two weeks prior to the year schedule, when students have classes of Language usage, Instrumental English (usage of technical English), Mathematics (review of high school content) and Psychology (aspects of competitive and demanding pressure environment).

So the program design is as follows:

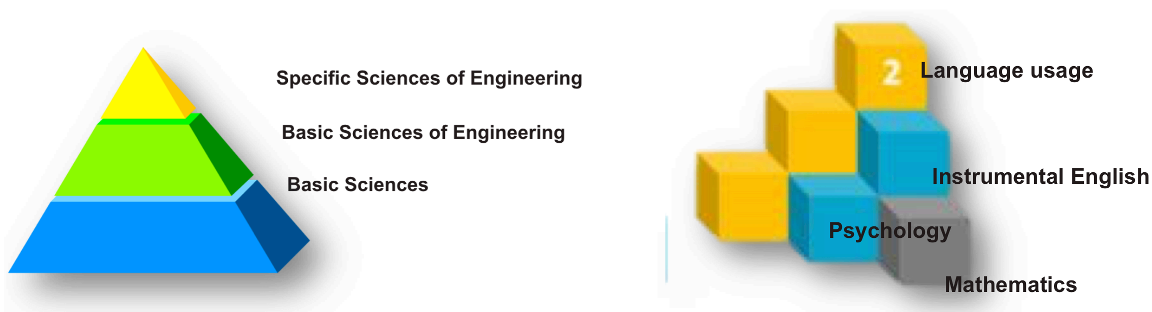

Fig. 1. Block of Different Courses that were added in a period that has been named as Pre-Program

5. THE CURRICULUM

Bellow, there is a chart of the basic cycle curriculum, that covers seven subjects in the first semester of the year of admission of the student in the Civil Engineering course and eight subjects in the second semester, totaling 27 credits in the first semester and 28 in the second semester. The content of subjects is taught deeply and with intense exercise sessions. It starts in the pre-program and lasts for all years.

Table 1. Basic Cycle Curriculum

	Discipline	CC	CW	TC	OC
1st	General Physics for Engineering I	4	0	4	

Semester	Experimental Physics for Engineering I	2	0	2	
	Introduction to Engineering Computing	4	0	4	
	Differential and Integral Calculus for Engineering I	4	0	4	
	Linear Algebra for Engineering I	4	0	4	
	Design for Engineering I	2	0	2	
	Introduction to Engineering	3	0	3	
	General Technological Chemistry	4	0	4	27
2nd Semester	General Physics for Engineering II	4	0	4	
	Experimental Physics for Engineering II	2	0	2	
	Numerical Calculus	4	0	4	
	Differential and Integral Calculus for Engineering II	4	0	4	
	Linear Algebra for Engineering II	4	0	4	
	Design for Engineering II	2	0	2	
	Mechanics I	4	0	4	
	Introduction to Materials Science for Engineering	4	0	4	28

CC – Credit class **CW** – Credit work **TC** – Total credits **OC** – Overall credits

6. FIRST RESULTS

2016 is the third year of this Civil Engineering program and the results are as follows.

Table 2. Civil Engineering Program

YEAR	Total of students that have entered in the Civil Engineering Program	Number of students of civil engineering that have opted for the Classical Engineering Program	% of enrollment rate
2014	180 students	89 students	49.44%
2015	180 students	100 students	55.56%
2016	180 students	136 students	75.56%

The table is based only on the enrollment number of students in the first and following years of program.

7. EXPECTED OUTCOMES

The initiative proposes specific learning outcomes and competencies such as:

- Applied learning: used by students to demonstrate what they can do with what they know;
- Intellectual skills: used by students to think critically and analytically about what they learn;
- Specialized knowledge: the knowledge students demonstrate about their individual fields of study;
- Broad knowledge: transcends the typical boundaries of students of higher education and encompasses all learning in broad areas through their solid knowledge in basic sciences and specific for engineering;
- Civic learning: enables students to respond to social, environmental, and economic challenges at local, national, and global levels [11].

8. DISCUSSIONS AND CONCLUSIONS

More than ever, it is necessary to form professionals equipped with tools that enable them to respond quickly to the changing work market and the unpredictable new professional expertise fostered by Scientific and Technological development. In fact, both, basic and applied engineering research, will be critical to the design and development of processes and systems on which every major sector of the country's economy depends. Both forms of research will be essential to meet the challenges and taking advantage of the opportunities that lay ahead.

While engineers are expected to be well grounded in the fundamentals of science and mathematics, they are also increasingly expected to acquire skills in communication, teamwork, adaptation to change, and social and environmental consciousness. The qualities most highly valued in graduates, beyond technical knowledge or skills, are: The ability to communicate well; a commitment to lifelong learning; the ability to adapt to an increasingly diverse world; the ability, not only to adapt to change, but to actually drive change. For this reason, a classic approach seems more useful for the demands of today's job market. It is at least interesting that the classic approach is being neglected, at a time when its product might be more interesting.

Currently, there are no surveys to determine if this group of students is better trained and/or has better skills, however it is estimated that during the internship period, they show better knowledge of mathematics, which seems to enhance their performance. This is the conclusion taken from the survey applied, every three months, to institutions which received students as interns, in which they grade students' performance during the internship. By better performance it means that students can cope better with the challenges and difficulties of problem solving and have a better understanding of the importance to search for the best solutions.

So far, the design and implementation of this program has been very positive. The first group of students, who will graduate in 2018, the students who are in internship at the 4th year have showed better performance, comparing to the other program, which is a first step to success. It means that the students have better grades, especially in the second and third years of the program so far. The Pre – Program, in special, has a good effect on students, since it provides them some elements that they can use such as Psychology and technical English.

The internship period, recommended in the 4th year of the program, has just started and the engineering college has been working to help students to find good training placements. It is crucial to advise them and to ensure proper conditions, in accordance with the law, in order to avoid waste of time and possible misuse of qualified labour.

This program, which is knowledge cantered, is responding very well in terms of students' enrolment and it is necessary to develop a survey to find out what are the elements that make students opt for this kind of education: the different approach, the strong knowledge basis or the possibilities of performing in any field of civil engineering, since the present job market is mutant and challenging. This shall be the next step for 2017, to develop a survey, which will allow us to refine the program and provide an input about the most relevant aspects of the program. Results shall be known at the beginning of 2018.

9. ACKNOWLEDGMENT

This work is financed by FEDER funds through the Competitivity Factors Operational Programme – COMPETE: POCI-01-0145-FEDER-007043 and by national funds through FCT – Foundation for Science and Technology within the scope of the project POCI-01-0145-FEDER-007136 and project UID/CEC/00319/2013.

Why Entrepreneurship education and training in Polytechnic of Porto graduated courses? Students' perception

Teresa Pereira, Pilar Baylina, Rafael Pedrosa
P.Porto, Portugal

ABSTRACT

This paper analyses the perception of Polytechnic of Porto (P.PORTO) students about entrepreneurship education in the graduated and training courses. A survey was conducted, supported by a questionnaire followed by researchers' guidance. The perception of entrepreneurship education and training in students' curricula was studied. Statistical analysis was applied using SPSS tool. Due to de diversity of graduated courses in P.PORTO it was possible to analyse the perception of students from different educational areas: Engineering, Health and Social Sciences. The main conclusion was that students from all courses seem to see entrepreneurship education and training as an important issue for their future career. As future work this survey should be applied to other P.PORTO units to have an integrated perception. The results of this study will be presented to courses coordinators to promote future curricula improvements.

Conference Key Areas: Please select three Conference Key Areas

Keywords: Entrepreneurship; Perception; Graduated education; Training; P.PORTO.

INTRODUCTION

In recent decades, and all over the world, there has been a growing interest in promoting entrepreneurship and innovation as there is evidence that entrepreneurship is crucial to economic recovery and growth, job creation, inclusion and poverty reduction, as well as innovation and competitiveness. Currently the political priority of Europe and European Union (EU) Member States is to take measures to incorporate entrepreneurship in the different society domains [1]. In the education field in the EU the importance of entrepreneurship in education was first published in the European Green Paper on Entrepreneurship In Europe [2], followed by the 2006 Recommendation of the European Parliament and Council related with key competences for lifelong learning, where 'sense of initiative and entrepreneurship' were identified as one of the eight key competences necessary for all members of a knowledge-based society [3]. Other important documents were published to promote initiatives across Europe such as the "Small Business Act for Europe in 2008" [4], the "Communication on Rethinking Education" in 2012 [5] and "Entrepreneurship Action Plan 2020" in 2013 [6]. All these documents promoted the implementation of several actions in Member States to incorporate entrepreneurship as competence in school curricula, vocational training and higher education, and to create frameworks and tools to operationalize in educational contexts. However, and after all these actions, there were no consensus about the components of entrepreneurship as competence. New efforts were developed and in 2015 the EU presented a report related with the development of a European Competence Reference Framework for the key competence "*sense of initiative and entrepreneurship"*[1], where entrepreneurship competences were analysed from several case-studies and resumed in larger themes and groups (*Fig.1*). It was also verified that competences associated with an entrepreneurial subject were related with entrepreneurship definition.

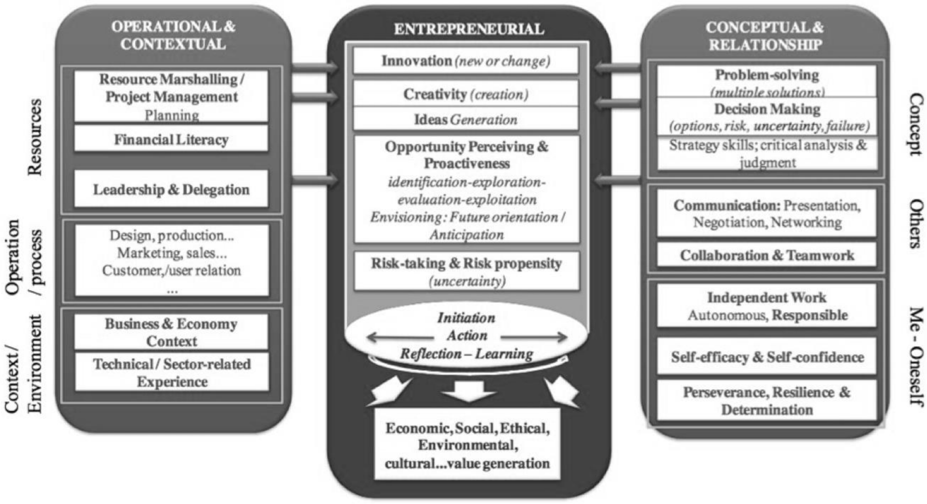

Fig. 1. Entrepreneurship Competences within larger themes and groups [1]

In 2016 The New Skills Agenda was presented to support a shared commitment and to work towards a common vision about the strategic importance of skills for sustaining jobs, growth and competitiveness. This agenda is centred around three main issues: 1) Improving the quality and relevance of skills formation; 2) Making skills and qualifications more visible and comparable; 3) Improving skills intelligence and information for better career choices [7]. The main aim is to promote a set of competences needed for personal development, social inclusion, active citizenship and employment. In this context the Entrepreneurship Competence study (EntreComp) was launched by the Joint Research Centre on behalf of the Directorate Framework to support the development of entrepreneurship competence at European level [8]. This framework consists of three interrelated competence areas: 'Ideas and opportunities', 'Resources' and 'Into action'. Each of the areas have five main competences along an eight-level progression model and proposes a comprehensive framework that can be used as a basis for the development of curricula and learning activities fostering entrepreneurship as a competence.

1 ENTREPRENEURSHIP IN P.PORTO

In the global context of the Academic Entrepreneurship (AE) [9], we have been observing that the Higher Education Institutions (HEIs), particularly Polytechnic Institutes (PI), have been developing, in an integrated way, several activities and initiatives for the development and promotion of innovation, research and entrepreneurship.

Concerning the P.PORTO, we had been participating from 2007 until 2014 on the previously mentioned nationwide initiative – *Poliempreende* – which is an ideas contest with training sessions included on the activities plan. These sessions are oriented for ideation and business plan development. This project emerges as an aggregator and cross-cutting initiative that had reinforced and complemented the different dynamics promoted in the P.PORTO, namely the master programmes and entrepreneurship classes (graduated and master degrees), with the goal to promote the spirit of initiative in students, the entrepreneurial willingness to create their own businesses and generate jobs, exploring the practical and professional character of their training and providing the participants with key skills related to creativity, innovation, planning of a business project, development of a business plan, setting up a business and its administration and management [10], as well as promote P.Porto AE.

The P.PORTO has promoted this contest for seven years continuously, always with very interesting numbers of effective participation of its community. Simultaneously the P.PORTO schools have been creating a formal entrepreneurship offer: curricular units in the several courses of HEIs; and masters, like Master in Entrepreneurship and Internationalization running in ISCAP of Porto. Since 2016 P.PORTO have been promoting the *Programa de Promoção do Empreendedorismo do P. Porto* (PPEPP), which has the same structure and pursues the same goals of *Poliempreende*.

In this context the main objective of this paper is to analyse the P.PORTO student's perception about entrepreneurship competences given by P.PORTO through the graduated courses and entrepreneurship training courses and programmes.

This paper is organized in four sections. The first one is an introduction contextualising the importance of entrepreneurship education in EU, in Portugal and in P.PORTO, and how it can contribute to fostering entrepreneurship, new companies, consequently more jobs and an increase of the economy of the regions and country. The second section presents in detail the methodology used to gather data and analysis. The third section presents the data treatment results and discussion. Finally, the main conclusions and future research developments are in the fourth section.

2 METODOLOGY

The methodology used is a Case Study which includes a literature review on entrepreneurship education and a survey with the development of a questionnaire (Google Forms platform) applied to several schools of P.PORTO: ISEP, ESS, ISCAP and ESTG. The questionnaire was addressed to students of the last year of graduated courses and master's courses and was developed to answer the main question: "What is the Students' perception about Entrepreneurship education and training in Polytechnic of Porto graduated courses?". Data collected was subject to a Statistical Descriptive Analysis and Exploratory Data Analysis with Principal Component Analysis (PCA) and Factor Analysis (FA).

The construct questionnaire is composed by these six major sections, each one with a set of questions. The first one (S1) to collected data from the respondent: School, course, year, gender and age; The second one (S2) about entrepreneurship fostering factors perception by the student; A third (S3) about the perception of competences given by the graduated courses that students attend; A fourth (S4) about competences given by P.PORTO through training courses and entrepreneurship programmes; A fifth (S5) about the students' perception from P.PORTO programmes; and a sixth (S6) concerning to the entrepreneurship internet platform used. The S2, S3 and S4 questions are based on the recommendations identified from literature [1,8], and a 1-5 Likert scale was used to answer (1-totally disagree, 2-disagree, 3-neither agree or disagree, 4-agree and 5-totally agree) (see *Table 1*).

Table 1. Questions in the survey

Section 2-Factors to fostering entrepreneurship
Q7- Have technical and management skills in the project area
Q8- Have own financial capacity
Q9- Plan my project and define the business model and target market
Q10- Have access to funding/incentives from third parties
Q11- Have appropriate partners
Section 3- Entrepreneurship Competences given by the curricula
Q12- Business Plan and Model
Q13- Project Management
Q14- People Management (employees, shareholders) and Relationships (customers, vendors)
Q15- Notions of Finance
Q16- Notions of Organization Management
Q17- Notions of Marketing
Q18- Notions of Leadership and Communication
Q19- Understanding Legal Issues
Q20- Notions of Entrepreneurship and Innovation
Q21- Understanding Industrial Property (patents, trademarks, logos)
Section 4- Entrepreneurship competences to be given by P.PORTO programmes
Q22-Development of the business plan and business model
Q23- Notions of Finance
Q24- Notions of Marketing
Q25- People Management (employees, shareholders) and Relationships (customers, vendors)
Q26- Notions of Entrepreneurship and Innovation
Q27- Understanding Legal Issues
Q28- Understanding Industrial Property (patents, trademarks, logos)
Q29- Project Management
Section 5- P.PORTO entrepreneurship actions students' perception
Q30- Know the training provided by P. PORTO under the Entrepreneurship and innovation framework programme (POLIEMPREENDE/PPEPP)? Yes or No
Q31- Training actions in P. PORTO about entrepreneurship and innovation are suitable in terms of periodicity
Q32- Training actions in P. PORTO about entrepreneurship and Innovation will meet my needs
Q33- Themes that are addressed in the training sessions are interesting and appropriate for the achievement of my project
Q34- I have the necessary conditions to attend to extra-curricular training
Q35- The training courses on Entrepreneurship and Innovation are a complement to the curriculum of my graduated course
Q36- Instruments/tools are given to facilitate my participation in entrepreneurial projects
Q37- These training courses are an additional weight on my individual training, in terms of time and work
Q38- These training courses and graduated activities are adequately in line.
Q39- These training courses should be performed outside the graduated courses period
Q40- The number of sessions is suitable
Q41- Training courses have appropriate disclosure
Q42- These training courses should be made with the joint participation of students from different Schools to promote synergies
Q43- The existence of the *OTIC* (Technology Transfer Office) in P. PORTO contributes to support entrepreneurship and innovation actions
Q44- Internet platforms to support entrepreneurship and innovation are important
Section 6- P.PORTO Entrepreneurship Platform INNOENTRE
Q45- Knowledge of the internet platform "INNOENTRE" Yes or No
Q46- The INNOENTRE internet platform used by P. PORTO to support Entrepreneurship and innovation has useful content
Q47- The INNOENTRE internet platform is easy to use ("user friendly")

2.1 Sample and Data collection

The questionnaire was distributed by email, using Moodle platform, to the students in May 2017, and 148 valid responses were obtained from a total of 262 registered students (a responding rate of 56,5%): 51,4% from ESS% (mainly from Pharmacy and Physiotherapy courses), 30,4% from ISEP (from Industrial and Management Engineering degree and Industrial Management engineering master course),16,9% from ESTG (from Economics Sciences course) and 1,4% from ISCAP (Master course on Entrepreneurship). Concerning the gender, 68,2% of the students are female and 31,8% male. The students' age ranged from 19 to 48 years old, most of them, 70%, between 19-23 years old.

2.2 Statistical Analysis

Statistical analysis was made using IBM SPSS software tool pack, version 24. Descriptive statistical analysis was used for quantitative nature data. Cronbach's alpha was used to measure the internal consistency. For the main questions from S2, S3 and S4, with twenty-three variables respectively, it was used the PCA and FA models. MacCallum *et al*. [12] recommend a minimum sample size of 100 responses and Guadagnoli and Velicer [11] refer a minimum of 100 to 200 observations, which is also recommended by several authors [11, 12, 18]. MacCallum *et al*. [13] define that, as a rule, for the sample size a ratio of valid responses per existing variables should be greater than 5 (6,43 in our case).

PCA and FA are exploratory multivariate analysis techniques that turns a set of correlated variables into a smaller set of independent variables, linear combinations of the original variables, known as components and factors. After performing the Varimax matrix rotation, the PCA becomes FA. If most of the total population variance can be attributed to the first components, then these can replace the original p variables without much loss of information [14]. The principal components are the uncorrelated Zi which are measuring different dimensions of data, ordered by decreasing variances. The variances of the principal components are the eigenvalues Yi of the sample of covariance matrix S, or of the correlation matrix R. When doing PCA, there is always hope that the variance of almost of the indices are negligible [15]. Both techniques are usually seen as data reduction methods but, beyond this goal, one of the main advantages of each one is that they allow to reduce the information of multiple correlated variables into one or more independent linear combinations (components or factors), representing most of the information present in the original variables [16,17]. Although PCA is usually applied to quantitative analysis, SPSS has implemented an optimal scaling procedure that assigns a numerical value to each category of ordinal variables and creates a corresponding quantitative variable with metrics properties, enabling PCA to be performed on categorical variables [16].

3 RESULTS AND DISCUSSION

The Cronbach's alpha for our variables was 0,933>0,8, that is considered very good [18]. Descriptive statistical analysis was used for quantitative nature data. For qualitative data, the PCA method and FA model was used. Concerning that until question Q29, there are 148 valid responses. PCA and FA were done according to section 2.2. Five factors with eigenvalue greater than 1 were retained, as well as the five factors that cumulatively explained a 70,8% variance in the original data. To clear data, the Varimax rotation was made (see *Table2).*

Communalities show that all variables have a strong correlation with extracted factors, since common variance of extracted variables is greater than 50%. F1- entrepreneurship Competences given by curricula (41,4%), explained by Q12 to Q21; F2- entrepreneurship competences to be given by P.PORTO (12,4%), explained by Q22 to Q29; F3- factors to fostering entrepreneurship concerning students' skills (7%), explained by Q7 and Q9; F4- Factors to fostering entrepreneurship concerning students' third financial access and appropriated partners (4,6%), explained by Q10 and Q11; F5- Factors to fostering entrepreneurship concerning students' own financial capacity (5,4%), explained by Q8, the others factors with less than 29,2% of variance explained. Concerning to Q12, Q22 and Q26 the allocation to a single factor is unclear, since the value is high for both factors F2 and F3, being higher in F2, where allocated.

Table 2. Rotating matrix of component

Questions	Component					communalities
	1	2	3	4	5	
Q7			**,463**			,501
Q8					**,903**	,843
Q9			**,793**			,721
Q10				**,728**		,699
Q11				**,816**		,745
Q12	**,632**		,434			,615
Q13	**,747**					,708
Q14	**,796**					,670
Q15	**,771**					,778
Q16	**,796**					,759
Q17	**,747**					,690
Q18	**,742**					,590
Q19	**,733**					,656
Q20	**,751**					,712
Q21	**,743**					,629
Q22		**,689**	,409			,749
Q23		**,805**				,745
Q24	,353	**,718**				,702
Q25		**,716**				,659
Q26		**,716**	,429			,753
Q27		**,842**				,822
Q28		**,824**				,741
Q29		**,822**				,802
% of variance explained	41,4%	12,4%	6,96%	5,4%	4,6%	
eigenvalues	9,51	2,86	1,601	1,242	1,068	

The Bartlett's sphericity test provided a very significant result ($\chi 2 \approx$ 2198,216; df253), featuring a *p*-value less than 0,001, value by which we reject null hypothesis, concluding that all the variables are significantly correlated. The results obtained have granted legitimacy to the use of the PCA method, showing that the matrix contains a significant correlation between the twenty-three variables. We have a 0,888 Kaiser-Meyer-Olkin measurement (KMO), which is considered good when between 0,8-0,9 value [17].

From questions Q30, only 45 students knew the P.PORTO resources dedicated to support and promotion of entrepreneurship and responded to the remaining questions. Hence, only a quantitative analysis was made (see *Table 3*). As the median (50% of the students), the mean and the mode (most frequent value) is higher than 3, from which we can conclude that the students find the P.PORTO entrepreneurship programmes suitable with the degree and useful, although (Q37) near 87% of the students find it as an extra weight to their' tasks and duties.

Table 3. Questions follow yes on Q30, Likert scale from 1-5

	N Valid	Missing	Yes	No	(1-2)	3	(4-5)	Mean	Median	Mode	S.Dev

Q47	6	142			0	16,7	83,3	3,83	4,00	4	0,408

4 CONCLUSIONS

The results of a survey carried on P. PORTO is presented with the main goal to analyse students' perception about Entrepreneurship education in graduated and training courses. Students realized that their graduated curricula gave them some entrepreneurship competences but they found that all the competences listed in the questionnaire should be given by P.PORTO in more detail, through complementary training courses or in the graduated courses. The students found that is important to strengthen competences about business plans and economic viability of projects and marketing. In addition, students stress that beyond all the competences that P.PORTO can offer through the curricula or training courses, as technical skills, to have own money or access to incentives from third parties is the main key to be an entrepreneur. Only 30,4% knew about P.PORTO entrepreneurship initiatives or activities, although students found the P.PORTO entrepreneurship programmes suitable with the degree and useful (Q37), nearly 87% of the students find it as an extra weight to their' tasks and duties. Only 4% knew about the InnoEntre platform, a very low value, despite only it being used since this year in P.PORTO .
The results obtained are in agreement with expected results, showing the importance of promoting formal disclosure of information to promote AE initiatives. As a future work the application of the questionnaire in all P.PORTO courses will be stimulated in a more participative way by all schools in order to obtain a more integrated perception and to promote the comparative analysis between different areas of education of the different schools of the P.PORTO. With regard to engineering courses, it is expected to conduct an exhaustive comparative analysis between the various courses taking into account the specific needs of each course. The results from this research will be presented and discuss with courses coordinators to promote future curricula improvements related with Entrepreneurship.

Teaching Professional skills in Engineering Programmes: The Academic Perspective

A plan for using Phenomenography to explore academic conceptions of their role in developing professional skills in engineering students

ABSTRACT

Engineering graduates in today's world face a global industry where professional skills are as important as the intellectual prowess gained by obtaining a degree itself. The importance of these skills is abundant in literature, yet so too is an ongoing barrage from industry that Higher Educational Institutions (HEIs) are not developing sufficient professional skills within students [1].

This occurs against a background of accrediting bodies who have adopted programme outcomes which require employability/professional skills to be integrated into the curriculum. There is also evidence that many educators have attempted to employ innovative strategies, such as Problem Based Learning to expose students to opportunities to practice these skills. Why therefore, is there still a gap between what industry wants and what HEIs provide and whose fault is it? Industry may be demanding more than an academic can deliver, in an already overcrowded curriculum with dwindling funding, particularly in an Irish context [2-3]. To close the gap, academics may need to expose students to professional skills in every module. This paper proposes a research study to explore how academics conceptualise their role in developing professional skills in engineering students.

Conference Key Areas: Skills and Engineering Education, Engineering Education Research, Curriculum Development

Keywords: Professional Skills, Phenomenography, Academic Conceptions of Teaching, Approaches to Teaching Inventory

INTRODUCTION

The author's interest in preparing engineering students for a successful career in industry stems from personal experience of recruiting, mentoring and managing graduates in civil and structural engineering consultancies. The range of skills, abilities and values of each graduate was varied, and it became apparent that academic achievement, whilst important, was not the defining skill for achieving early responsibility or promotion within the company. More often, the graduate who could communicate well and self-direct his/her work was given more responsibility and opportunity.

The intent in this paper is to present a plan for a PhD research study with two aims. The first is to summarise the research plan and proposed methodology. The second is to elicit critique and advice in the design of the study, including the research questions and the methods proposed.

1 BACKGROUND

1.1 Influence of Accreditation Bodies and Industry

Accreditation requirements for engineering programmes serve as a framework for programme design. Several accrediting bodies including Engineers Ireland (EI), and the Accreditation Board for Engineering and Technology (ABET) require degree programmes to include outcomes, which incorporate what may be considered professional skills [4-5]. These skills include; self-directed working, teamwork, multidisciplinary working, ethics, communication with the engineering community and with society at large. The EI programme outcomes have been developed in consultation with employers and should therefore address concerns about professional skills from an employer's perspective. Employers in Ireland however, still report that they are not satisfied with the level of competence of engineering graduates in non-technical skills. [1]. This suggests therefore, that although there are processes in place which should ensure that students have opportunities to develop these skills, there is a disparity between what the accreditation paperwork requires and the skills that students actually develop. One area where this disjoint may occur is in the classroom, and could be influenced by how the academic teaches or how the students learn.

1.2 Academic Conceptions of Teaching

Several studies report that although there is an awareness of the importance of developing non-technical skills within students, academics do not always feel adequately prepared to teach these skills, nor feel compelled to change their teaching pedagogy [6-10]. If we assume that academics are a key driver for change in engineering education, then we need to ascertain what constitutes good teaching or more importantly good learning in relation to developing professional skills. The theory of academic conceptions of teaching provides a lens through which to consider this aspect. When academics enter the classroom, they do so with prior conceptions of what constitutes good learning and teaching in their discipline. Prosser and Trigwell [11] purport that the academic's conception of teaching has a direct influence on how the students learn. Since this theory emerged in 1991, several researchers have produced varying categories of descriptions of the conceptions of teaching [11-14]. Prosser and Trigwell went a step further and created an Approaches to Teaching Inventory (ATI) survey instrument [11]. This can be used to identify which category best describes each survey respondent in a particular teaching context.

At the lowest level, the emphasis is on transmission of information and teacher focussed strategies with the result that students respond by accumulating information and rote learning. The highest category signifies a conceptual change and student focussed approach where teachers focus on their students' own views or conceptions of the subject, rather than their own [11]. In this category, teaching pedagogies would likely include open discussions and debates so that students take ownership of their own views. One could conclude that the ability to critically examine an issue and defend a position requires practice in several of the professional skills that employers are seeking. One aspect of this research study intends to explore if the academic conceptions of teaching bear any relation to how academics feel about teaching **professional skills** in particular.

2 RESEARCH QUESTIONS

The research questions centre around the experience of the academic in the classroom, although we are also interested in factors which may have influenced how the academic contemplates the relative importance of professional skills. This includes how the academic approaches teaching in general (with reference to the ATI) and previous training in different pedagogical approaches. The authors' background has influenced their own views on professional skills and so we want to investigate if academics with an industrial background have different views to those who have a purely academic background. This research study has three interlocking aspects as shown in Fig. 1.

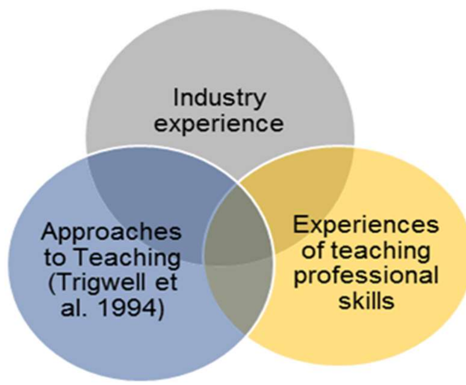

Fig. 1. Interlocking aspects of research study

The overarching research question is;

- What are the qualitatively different ways that academics experience and conceptualise teaching in engineering programmes in Ireland?

Sub-questions focusing on professional skills include;

- What are the qualitatively different ways that academics perceive what is meant by professional skills in engineering? How is the term 'professional skills' understood by engineering academics? What is the variation in academic's conceptions of what 'professional skills' mean?
- How do academics manifest their conceptions of teaching through their actions in teaching professional skills?
- What is the relationship (if any) between conceptions of teaching and academics' background in academia, industry or both?
- What is the relationship (if any) between conceptions of teaching and experiences of teaching professional skills?
- What is the correlation (if any) between conceptions of teaching professional skills and academic's backgrounds in academia, industry or both?

3 METHODOLOGY

3.1 Brief description of Phenomenography

The aim of the study is to build an understanding of academics' conceptions, perceptions and experiences of teaching professional skills. It is not to prove a hypothesis, to look at a particular case study nor a particular group of people. A descriptive method of enquiry was needed. Three research approaches were considered appropriate for the study; phenomenology, phenomenography and grounded theory. We determined that phenomenography would best answer the research questions.

Phenomenographers seek qualitatively different, but logically and hierarchically interconnected descriptions that a group of people experience in relation to a particular context [15]. Ference Marton, the original proposer of the term phenomenography, relates action and experience [16]. It follows that if we want to understand how people **handle** certain situations then we need to investigate how they **experience** those situations. "A capability for **acting** in a certain way reflects a capability **experiencing** something in a certain way. The latter does not cause the former, but they are logically intertwined" [16, p.111].

Phenomenography is proposed as an ideal fit for this research study for two reasons. Firstly, we believe that there are varied ways in which academics perceive, conceptualise and experience teaching professional skills. It is the variation we are interested in, not the commonalities which would be typical of a phenomenological study. The second reason is that a phenomenographic study is usually context bound. It refers to a particular instance that the interviewee is asked to reflect upon. We intend to investigate their experiences in relation to a particular context and not as an idea of teaching professional skills in the abstract.

3.2 Rationale and use of phenomenography in this research

This study aims to effect change in the way students are prepared for industry, particularly in relation to professional skills. This aligns well with the origins of phenomenography which was based in an educational setting. The study, while arguably based in education, focuses not on students but on the experiences and conceptions of academics.

There is merit in this approach as it is argued that previous research studies in science education have sought to develop prescriptive solutions to problems in teaching and learning and that this is not effective, that descriptive results are much more powerful [17]. Phenomenography allows us to look at how academics approach their teaching in a natural setting and how these approaches affect the outcome for students. Research output in a descriptive form will allow academics to reflect critically on their own practice, which can account for their own individual perceptions [17].

Despite initial assertions to the contrary [16,18], phenomenography can be considered a research approach, and the researcher uses whatever research methods most appropriate to the study. In this instance, we will undertake a two-phase approach. Phase One will comprise an online survey, the primary purpose of which is to collect background information on the participants forming the population sample. The survey responses will set the context for the research and will inform the interview questions for the main phenomenographic study, which is undertaken in Phase Two. Fig. 2. outlines the conceptual framework proposed for the research study.

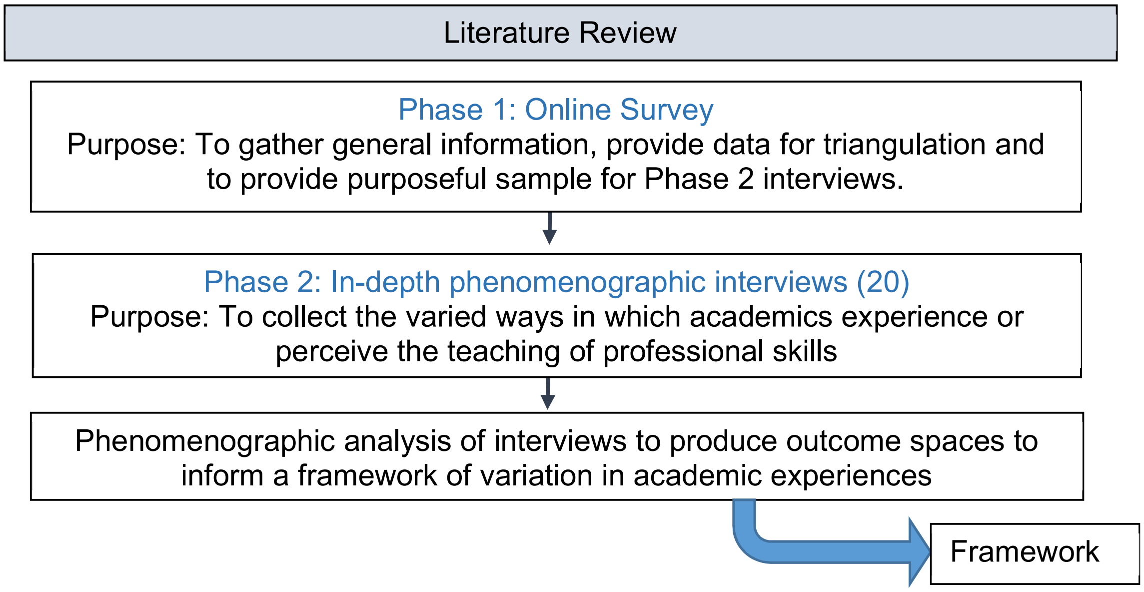

Fig. 2. Conceptual framework of research study showing key milestones

3.3 Data Collection – Phase 1 Online Survey

The primary purpose of the Phase 1 online survey is to enable us to undertake purposive sampling for the Phase 2 (interview phase) of the study. However, it will also be used to assess engineering academics' attitudes towards learning and teaching in general using the Approaches to Teaching Inventory (ATI) [11]. This will allow us to compare and contrast against existing data banks for other disciplines.

3.4 Survey questions

The survey aims to collect information in the following categories:

- Gender
- Professional qualifications (both academic and professional organisations)
- Background career (engineer or other)
- Extent of industrial experience (what level; recruitment or mentoring of graduates)
- Extent of academic experience (what level; responsible for programme design)
- Previous experience of an accreditation event
- Ranking of the skills required to make a **good** engineering graduate.

As the survey will include both closed and open questions, quantitative and qualitative analysis will be possible. In particular, the following aspects may be analysed;

1. What percentage of academics have industry experience and furthermore were responsible for recruiting and/or mentoring graduates in industry?
2. What percentage of academics who teach engineers are engineers?
3. What percentage of academics believe that they only teach technical skills?
4. How does the ATI for engineering academics differ to other disciplines and is there a statistical significance between academics who have an engineering degree compared to others, or academics who have worked in industry compared to those who have not?
5. Is there a statistical difference between ATI for male and female academics?

6. What are the top 10 ranked professional skills for engineering graduates of today?
7. What percentage of academics have undertaken a teaching qualification? Is there a relationship between obtaining a teaching qualification and responses to the ATI?

3.5 Survey Method and Sample

The survey will be distributed electronically to all academics teaching on engineering programmes in all HEIs in Ireland. Only the author's own School will be excluded to avoid ethical issues [19]. A pilot survey will be trialled with respondents selected as meeting the requirements of the sample, but who will not be included in the final survey. They will be asked to give feedback on all aspects of the questionnaire including content, language, length and any ambiguity in the questions. In particular, the terms used in the question on ranking of professional skills will be reviewed in detail and these may have to rephrased in order to extract the type of answers we intended.

3.6 Research Participants

It is important that the interviewees selected for the data collection are appropriate to the purpose of the research, by representing a large cross section of views about the research topic. A purposeful sample (research participants relevant to the central question) and maximisation of sample variation (broad range of views) is preferred [20]. It is important to select interviewees who offer what is described as "the best opportunity of manifesting the full extent of the various ways of experiencing the phenomenon" [21, p.6]. One opinion is that the researcher must not be swayed by being inclusive of gender or other cultural groups, which are in a phenomenographic sense, artificial distinctions. However, other researchers argue the opposite; that emotional responses are important and differ between the genders and "it would be useful for the phenomenographer in considering a purposive sample to include gender as a basis for ensuring adequate variation, to attend to sex differences in the analysis, and to choose to explore areas of learning central to women's as well as men's experiences" [22, p.224]. The sample for Phase 2 interviews will be selected bearing in mind the different facets of the research questions asked.

3.7 Data Collection – Phase 2 Interview Methodology

Whilst some texts suggest 25-30 interviews are required [20], others suggest that saturation can be achieved with 10-20 interviews [23]. It is initially intended to undertake 20 second stage interviews in addition to pilot interviews with two people who will not be included in the sample. The interviews will be undertaken by one researcher "in order to promote consistency in questioning and in the ways in which the responses are prompted and contrasted" [20, p.58].

3.8 Analytical Methods

Phenomenography aligns with a subjective ontology, where the researcher interprets the outcome of interviews with people. It is accepted that the people will construe the world in different ways, as opposed to there being one truth. In fact, in phenomenography, researchers do not make any assumptions about reality, nor do they intend that their research outputs represent the **truth**. The findings of a phenomenographic study are presented in outcome spaces; hierarchically ordered sets of categories of descriptions, identified by qualitatively different variations of experience of the phenomenon. Researchers aim to present outcome spaces that reflect the phenomenon, but researchers can only provide more or less complete outcomes, not right or wrong outcomes [23].

Through uncovering variation, we hope to identify different **categories of description** which show **themes of expanding awareness** of how teaching professional skills is conceptualised by academics. The hope is that the outcome spaces can show academics that there are **more complete ways** of conceptualising how we can teach professional skills and that this will encourage greater adoption by academics, even within technical subject areas.

4 SUMMARY

In this paper, we have provided a brief overview of a proposed PhD research study to elicit feedback from educational researchers in the field. We hope that the research we are about to conduct will contribute to placing increasing importance on teaching of professional skills. We hope that the outcomes will provide a framework for academic staff to reflect upon their own approach towards teaching professional skills in an engineering curriculum.

Quality Assurance and Accreditation

Revision of the Qualification Framework at the Technical University of Denmark
Part 1: Concepts

K.-A. Henneberg
Associate Professor, Ph.D.
Dept. of Electrical Engineering, Technical University of Denmark
Kgs. Lyngby, Denmark
E-mail: kah@elektro.dtu.dk

ABSTRACT

When the Technical University of Denmark (DTU) adopted the National Qualification Framework (NQF), it was implemented as an add-on to the existing concept in place for describing educational outcomes, rather than by redesigning the educational outcomes themselves. The system in place does not emphasize the type and extent of knowledge, skills, and competencies adequately to facilitate programme development and evaluations. In this work, an expansion and reorganization of the qualification elements in the NQF at DTU is proposed as a means to facilitate a more detailed design and evaluation of the educational programmes. The top level categories of *knowledge*, *skills,* and *competencies* are reorganized into four categories: *-to know*, *- to be*, *-to interact*, and *–to do*. Knowledge of praxis is a new element in the category *–to know*. The new category, *-to be*, includes mind-set development and self-instruction. The category, *-to interact*, includes competencies in communication and teamwork. The category, *-to do*, includes operative skills and competencies in problem solving. Each of the four main categories contain a number of qualification elements. Suitable taxonomies are suggested for each of the main categories.

Conference Key Areas: Curriculum development, Quality Assurance and Accreditation, Engineering Skills

Keywords: Qualification framework, educational outcomes, constructive alignment

INTRODUCTION

When the Technical University of Denmark (DTU) adopted the Danish National Qualifications Framework [1] (NQF), the new concept of *knowledge*, *skills,* and *competencies* was implemented as an add-on to the existing set of qualifications. Each educational programme constructed a qualification matrix with the existing qualifications listed vertically and the NQF descriptors *knowledge*, *skills,* and *competencies* as the horizontal axis. However, the application of only three descriptors has proven to provide inadequate detail in all aspects of programme design, implementation and evaluation. In this paper, we propose a revision of the *knowledge*, *skills,* and *competencies* categories and present a number of taxonomies aimed at the different types of qualifications. In a companion paper [2], applications are demonstrated for three B. Sc. in Engineering programmes.

1 EXPANSION OF THE QUALIFICATION FRAMEWORK

The NQF organizes qualifications into three descriptors: knowledge, skills, and competencies. UNESCO [3] uses four descriptors: *to know*, *to be*, *to cooperate*, and *to do*. In this section, these approaches are combined to form a revised qualification framework.

1.1 Current framework

The current descriptors of the NQF for programmes at the Bachelor of Science (B. Sc.) level are listed in *Table 1.*

Table 1. Descriptors of the Danish National Qualification Framework [1]

Knowledge	1	Must have knowledge about theories, methods, and praxis within one or more disciplines or professions.
	2	Must be able to understand and reflect on theories, methods, and praxis.
Skills	3	Must be able to apply methods and tools associated with one or more disciplines and be able to apply general skills required by employees in a discipline or profession.
	4	Must be able to interpret theoretical and practical problems and apply relevant methods for analysis and problem-solving.
	5	Must be able to communicate the nature of problems and their solutions to peers as well as to non-specialists.
Competencies	6	Must be able to handle complex entrepreneurial challenges in study and work situations.
	7	Must be able to work independently and to cooperate in groups in a professional manner.
	8	Must be able to identify personal need of learning and to orchestrate self-instruction in different learning contexts.

The NQF contains eight educational levels with Bachelor of Science ranked 6, Master of Science ranked 7 and the Ph. D. as the eight and top level. In an indirect manner, the NQF thus represents a taxonomy for educational outcomes. The NQF does not offer a taxonomy for measuring progression in learning within each such level. This is one reason for developing a qualification framework aimed specifically at the B. Sc. in Engineering programme. Another reason is the absence of a clear distinction between skills and competencies. While descriptor number 3 fits the category of skills very well, descriptors number 4 and 5 are indistinguishable in nature from descriptors 6, 7, and 8. Descriptors number 4 and 6 are both about problem solving and could be merged into one descriptor. Placing descriptor number 5 about communication within the skills category is also questionable. Another accepted opinion is that mastery of languages is a skill, while communication of professional matters is a competency. Finally, the NQF fails to address the development of a personal and professional mind-set.

1.2 Revised framework

Besides rectifying shortcomings in the current NQF mentioned above, a revised framework must also facilitate constructive alignment by defining qualifications that are equally meaningful at the programme level and at the level of individual courses. A third objective of a revised framework is to facilitate a more systematic use of taxonomies as a linkage between programme outcomes and course outcomes.

Table 2 defines the top two levels of the revised qualification framework. The three major categories based on knowledge, skills, and competencies have been abandoned in favour of four categories similar to UNESCO's *Four pillars of learning* [3]. The first category, - *To know*, is essentially identical to the knowledge category in the NQF. The second category, - *To be*, is a new addition, emphasising development of a personal and professional mind-set. This category, by some referred to as the *Disciplinary future self* [4], includes the notion of *Life long learning*, which here has been renamed *Self-instruction* in order to strengthen its relevance in the minds of young students. The third category, - *To interact*, includes communication as well as teamwork, and is therefore similar to the notion "Learning to live together" in UNESCO's *Four pillars of learning*. The fourth category, -*To do*, is the combination of operative skills and problem solving. The most noticeable change in the organization of the revised qualification framework is the significant narrowing of the definition of skills and its closer association with problem solving. This closer association is motivated by the taxonomy for problem solving presented in the next section.

Table 2. Components of a revised qualification framework

1st level	2nd level descriptors	Description
1: - To know	Knowledge of theories	Acquire and apply terminology and facts, theories, laws of nature, methods, and procedures.
	Knowledge of praxis	Apply knowledge about praxis-induced boundary conditions and their influence on the applicability of theories and methods.
2: - To be	Mind-set	Develop a personal and professional mind-set.
	Self-instruction	Identify need for new knowledge, gather resources, execute, and evaluate learning outcomes.
3: - To interact	Teamwork	Conduct, coordinate, lead, monitor, and develop teamwork.
	Communication	Master language and tools, structure content, choose between narrative styles, edit for logic and clarity, and define communication objectives and receiver competencies.
4: - To do	Operative skills	Advance degree of training, from novice to expert, in executing manual and cognitive tasks.
	Problem solving	Interpret problem information, identify objective, diagnose problem, choose strategy, execute and evaluate solution, interpret impact of solution.

2 QUALIFICATION CATEGORIES AND THEIR TAXONOMIES

A qualification framework serves not only to define educational outcomes but also to construct an alignment between outcomes at the programme level and at the level of individual courses. A qualification framework must also take into consideration the learning processes facilitated by the courses and it becomes necessary to distinguish between learning objectives and learning processes. The complexity of learning objectives and the complexity of learning processes cannot be described by a single taxonomy.

2.1 Object and process complexity

Academic complexity follows the scholarly advancement semester-by-semester from introductory courses to more advanced courses in the final year of a programme. We will refer to this dimension of complexity as *object complexity*. The complexity of the processes engaged in acquisition and use of knowledge is here referred to as *process complexity*. Bloom's taxonomy (*Figure 1*) for the cognitive domain [5] is one of the most used taxonomies for measuring process complexity.

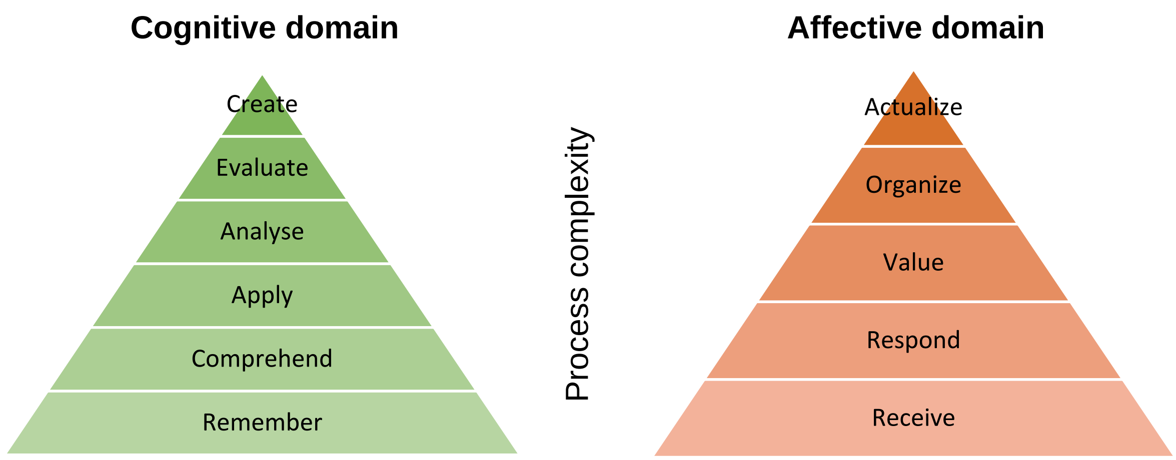

Figure 1. Bloom's taxonomies for the cognitive [5] and affective domains [6]

Bloom's taxonomy for the cognitive domain only describes the process complexity in acquiring and using knowledge. This taxonomy is thus not suitable for defining the topic complexity of the individual courses within a program. To document progression in topic complexity from the beginning to the end of a programme, a course hierarchy scale is needed (see *Table 3*).

Table 3. Course level hierarchy

Course levels	Description	Characteristics
4. Capstone	Projects, capstone design, internships, and thesis work	Non-taught programme activity.
3. Discipline specialization	Intermediate level studies in sub discipline.	Elective course aimed at a subpopulation of students within a programme. Has *Discipline core* courses as its prerequisites.
2. Discipline core	Discipline specific foundation courses.	Unique to a specific programme. Has *Generic foundation* courses as its prerequisites.
1. Generic foundation	Discipline independent courses.	Shared between many programmes.

Courses at the *Generic foundation* level are introductory courses, often with no prerequisite courses, typically first-year courses in natural science. *Discipline core* courses are first level engineering courses, which only have introductory natural science courses as their prerequisites. Such courses typically have little or no inter-dependencies. At the *Discipline specialization* level we place second level engineering courses, where each course may have several first level engineering courses as their prerequisites. A course in instrumentation typically embraces both analogue and digital electronics as well as programming and a course in biomaterials embraces cell biology and materials science. At the top of the course ranking, *Capstone courses* are project courses, capstone design courses, internships and thesis work.

2.2 –To know

The qualifications in the category, *–to know*, is founded on Krathwohl's elements of knowledge [5], but extended with *knowledge of praxis* (*Table 4*).

Table 4. Qualification elements of knowledge

Knowledge elements	Description
1.5 Metacognitive knowledge	Knowledge of cognition in general and awareness of one's own cognition.
1.4 Knowledge of praxis	Knowledge of praxis or regulatory induced limitations to application of theories, methods, and materials within relevant disciplines.
1.3 Procedural knowledge	Knowledge of procedures and methods and the criteria for their use.
1.2 Concepts	The interrelationships among the basic elements within a larger structure that enable them to function together.
1.1 Facts and terminology	The basic elements required to be acquainted with a discipline or to solve problems in it.

The elements of knowledge in *Table 4* are organized from low to high level of complexity and should be considered to have cumulative dependencies. They form one axis in a *knowledge-qualification matrix* and the levels of Bloom's taxonomy for the cognitive domain forms the other axis. Thus, with respect to acquisition and use of knowledge, course instructors should not only aim high on Bloom's taxonomy for the cognitive domain but also aim high on the scale of knowledge elements (*Table 4*). Both scales in the *knowledge-qualification matrix* are independent of topic complexity, hence first semester courses should aim just as high as last semester courses.

2.3 –To be

The elements of mind-set development are divided into two major categories, personal mind-set and professional mind-set (*Table 5*).

Table 5. Qualification elements of mind-set

Mind-set	Components	Description
Professional mind-set	6. Product-oriented	Embedded value set founded on safety, reliability, sustainability, usability, serviceability, aesthetics and ethics.
	5. Process-oriented	Hypothesis and needs driven curiosity, evidence based creativity, logical and critical thinking.
Personal mind-set	4. Self-instruction	Curiosity, self-reflection, need-awareness, resourcefulness, competence-oriented, metacognition.
	3. Self-governance	Vision, self-consciousness, receptiveness, competence-oriented learner, priority-setting.
	2. Social attitude	Empathy, tolerance, reliability, moral and ethics.
	1. Self-efficacy	Initiative, decision-making and responsibility.

The elements have been enumerated by the chronological order in which these components typically enter the mind-set of an engineering student, and represent increasing levels of *qualification element complexity.* The *process complexity* of mind-set development is measured by Bloom's taxonomy for the affective domain (*Figure 1*). Tacit, but strategic enforcement and monitoring is required to obtain a satisfactory development in all students. The top three mind-set levels (Self-instruction, Process-oriented and Product-oriented) must be integrated into courses in an explicit manner.

2.4 –To interact

The third category, - *To interact*, includes communication and teamwork. *Table 6* describes elements of oral and written communication in order of increasing element complexity.

Table 6. Qualification elements of communication

Element complexity	Element description
5. Context analysis	Define communication objectives and analyse receiver competency.
4. Narrative style	Choose between multiple narrative styles in accord with context.
3. Quality control	Edit grammar, style, logic, clarity and sources.
2. Structure of content	Structure content according to standards.
1. Language and tool skills	Master language and information technology tools.

Table 7 describes elements of teamwork in order of increasing complexity.

Table 7. Qualification elements of teamwork

Element complexity	Element description
5. Development	Develop team processes as well as personal growth in the team members.
4. Monitoring	Monitor team processes and team members' adherence to defined codes.
3. Definition	Design time schedules and define codes of behaviour, efforts, ethics, and accountability.
2. Coordination	Coordinate tasks and resources.
1. Execution	Work in teams with individual tasks and adopt codes of behaviour, language, effort, deadlines, and accountability.

In order to embrace the qualification elements of communication and teamwork, engineering programmes must include courses with considerable time allocated to student-centred learning activities. At DTU, such programme elements are mandatory at the first, fourth, and sixth semester in the B. Sc. programme.

2.5 –To do

The qualification category, -*To do*, includes operative skills and problem solving. *Table 8* describes a taxonomy for operative skills based on work by Dave [7]. Dave's taxonomy is used here to express levels of training, from novice to expert, in both manual and cognitive tasks. When operative skills are not a prioritized teaching objective, some students will remain novices throughout their study. Glaser's method of *Shaping* [8] can be used to train operative skills.

Table 8. Qualification elements of operative skills

Taxonomy levels	Level description
5. Naturalization	The expert can discriminate between situations and visualize solutions while diagnosing the task.
4. Articulate	Learners see the goal and adapt procedures.
3. Precision	Learners choose when and how to apply rules.
2. Manipulate	Understanding the context, the learner starts to recognize additional aspects and alternatives.
1. Imitate	Learners rely strongly on guidance and rules they have been instructed to follow.

Table 9 describes elements of problem solving in order of increasing *element complexity* based on work by Plant et al. [9]. The lowest level of complexity is the step-by-step execution of procedures following outlines. Operative skills are the main prerequisite for this level. It is for this reason we have chosen to combine operative skills and problem solving into one qualification category, *-to do*.

Table 9. Qualification elements of problem solving

Element complexity [9]	Element description [9]	Learning activity
5. Create	Design of procedures that are new to the problem solver.	Projects, capstone design, thesis work
4. Interpretation	Interpretation of problem description, identification of objective, translation of the real problem to an idealised problem, evaluation of validity of solution to idealized problem, prediction of impact of solution on problem sphere.	Case studies Course embedded mini projects
3. Strategy	The task of choosing the best suitable procedure among several valid procedures.	Case studies Course embedded mini projects
2. Diagnosis	The task of choosing between correct and incorrect procedures for a specific problem.	Textbook problems
1. Procedure	Operations to be done step-by-step by following a procedural outline. Ability relies on possession of operative skills.	Textbook problems

The elements of *Strategy* and *Interpretation* are rarely met in problem solving activities based solely on textbook problems, regardless of the level of the textbook. Case studies and mini projects embedded in courses are better options. Inclusion of these two elements in the qualification framework will help close the gap between problem solving at the introductory level and at the final level of an engineering programme.

3 SUMMARY

A proposal has been presented (*Table 2*) for a revised qualification framework at DTU. The set of qualifications are organized into logical categories: *-to know*, *-to be*, *-to interact*, *-to do*, and the elements in the qualification framework are easily integrated into outcome statements for individual courses. A number of taxonomies have been associated with different categories of qualifications to facilitate instructional planning and execution in alignment with programme objectives. The proposed framework strengthens the focus on knowledge dimensions, on mind-set development and on operative skills. Finally, it embraces a method for designing problem solving activities to progressive levels of complexity.

In a companion paper [2], the elements of the proposed qualification framework are put into use to write Programme-Qualification Matrices for three different B. Sc. in Engineering programmes.

ABSTRACT

The aim of this article is to explore the pilot project dedicated to integration of internal quality system in the Strategy Development of Riga Technical University (RTU). Recent development of RTU has been mainly achieved due to the adopted RTU Development Strategy 2014 – 2020 and introduction of the European Foundation for Quality Management (EFQM) management model. RTU Strategy focuses on three pillars – high quality study process, research excellence and sustainable innovation and commercialization. RTU has introduced the EFQM management system as the basis for operations to support implementation of the strategy and to ensure process efficiency and quality. During this research, quantitative and qualitative analysis was performed. More than 150 experts and stakeholders participated in this research in order to evaluate the implemented pilot project. The proposed model and actions to introduce sustainable integrated concept are based on the Planning Stage, Approach, Implementation, Assessment and Refinement. The method how to define action plan priorities has been adopted to suit the needs of RTU. Results showed that this was

Conference Key Areas: Education Excellence for Sustainability, Sustainability and Engineering Education, Quality Assurance and Accreditation.

Keywords: strategy, EFQM model, sustainability, internal quality assurance

INTRODUCTION

In the current volatile and demanding business environment, managers are eager to demonstrate that their organizations are excellent, which can mainly be achieved through continuous performance improvement. Based on the assessment of organizations, the EFQM Excellence Model is the most frequently applied and suitable tool that shows how successful they are in ensuring organizational excellence. [1]

In the recent period, RTU has grown to become the biggest university in Latvia by the number of students. In Times Higher Education ranking RTU was ranked among top 500 universities in the world, and collaboration with industry was marked as the strongest pillar. RTU has established Design Factory which is part of global Design Factory Network aiming towards more entrepreneurship focused university. It is clear that organizations must have an appropriate management system to succeed in this path. [2] Basu states that quality can be explored considering three dimensions (Design Quality, Process Quality and Organization Quality). [3] The researcher reflects on the lack of attention dedicated to Organization Quality. Main challenges associated with introduction of quality systems at the institutions of higher education are connected with lack of motivation, unwillingness of staff and lack of qualified personnel [4]. Human resources are "the living resource" of organizations, and as such are present in the evaluation criteria of all excellence models [5]. Therefore, administration of RTU created a two level strategy – general university strategy and action plan as well as the strategy of each faculty. This article focuses on the EFQM model and the ways how it can be effectively integrated into the strategy to enhance sustainable education, research and valorization.

1 STRATEGY AND QUALITY SYSTEM DEVELOPMENT

1.1 Development of the university strategy

Strategy defines a path for organizational development. The major goals are included in the core strategy document, but wider range of indicators can be defined in the action plan [6]. Careful and planned approach to execution is important for successful strategy implementation, and that is the factor on which organizations fail the most [7]. Research conducted by Rapert, Velliquette, and Garretson [8] shows that reaching internal consensus allows organizations to achieve better financial results and increases efficiency. Additionally, many authors maintain that management is responsible for developing and sharing the vision, encouraging innovativeness, supporting employee efforts and involving employees in the decision-making process [9]. To define general strategic goals a university must have a clear understanding of what it needs to deliver and perform gap analysis to understand its current position [10]. Along with general strategic goals, the management should define horizontal priorities – groups of tasks, which will allow a university to reach the aims of the core priorities. Horizontal priorities can be grouped in sections (no more than 3-6) and they should be incorporated in the core processes as shown in Fig.1.

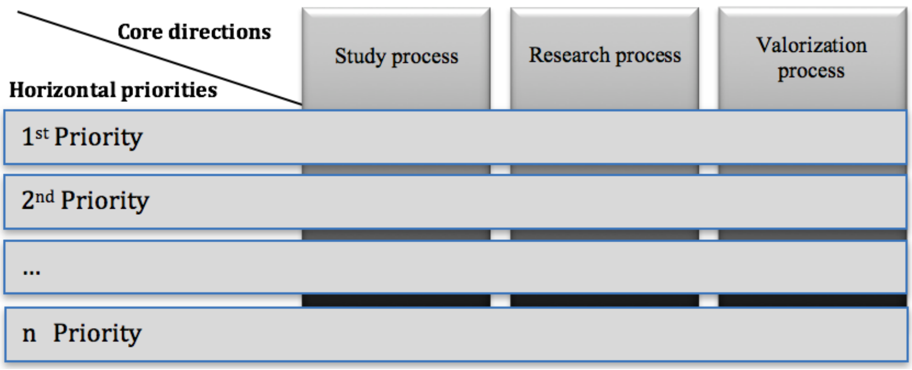

Fig. 1. Incorporation of horizontal priorities in the strategy.

1.2 Setting strategy KPI

Formulating its core action areas and defining general settings, a university sets the framework for all further actions and policies included in the strategy document. Academic and scientific personnel play an important role by setting the aims according to the existing tendencies and trends. When the requirements for reaching the desired strategic goals are set, the university should develop an action plan. These stages are integral elements of the process of university strategy development (Fig. 2).

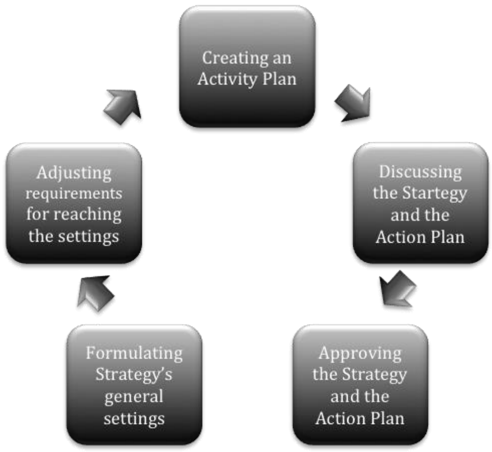

Fig. 2. Development of the Strategy and Action Plan.

To ensure the university's strategy is implemented effectively it is recommended to develop an action plan setting detailed strategic targets – KPI (Key Performance Indicators), based on which the university is able to plan clear tasks, select measurable indicators, appoint responsible units and set deadlines.

1.3 Strategy development at Riga Technical University

RTU has developed the strategy for the period of 2014-2020 (approved in October 2013) and has drawn up an action plan that sets the core priorities and detailed key performance indicators that allow monitoring strategy implementation. At first, management work group performed benchmarking and SWOT analysis. Based on the information obtained through benchmarking and SWOT analysis, the management work group together with the Rector worked on the mission that would reflect three core objectives of RTU – high quality study process, research and innovation, and commercialization. The work group introduced horizontal priorities, which include internationalization, interdisciplinarity, organizational efficiency, financial efficiency and infrastructure efficiency, and these priorities should have been incorporated in all three objectives as seen in Fig. 3.

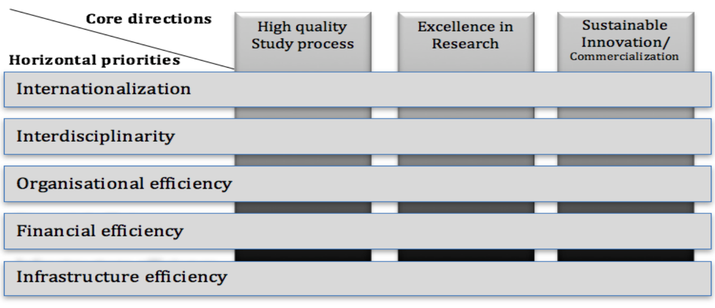

Fig. 3. Horizontal priorities of the Strategy of Riga Technical University.

1.4 Quality system concept in RTU

According to Calvo-Mora, Navarro-García & Periañez-Cristobal, organizations need to establish an appropriate management system to achieve success, irrespective of the sector, size or structure. [11] There are two ways in which firms in Western countries are addressing quality management issues. On the one hand, implementation and certification of quality management systems according to ISO 9000 standard are undoubtedly the most popular methodology. On the other hand, evaluations based on the EFQM are gaining ground in improvement processes. [12] As Escrig & de Menezes point out, the EFQM was launched in 1991 as a non-prescriptive framework based on nine criteria. [13] The present version of the model and respective weights are shown in Fig. 4. Each criterion encompasses several sub-criteria, thus leading to a total of 32 sub-criteria. RTU Quality System is based on the EFQM Excellence Model.

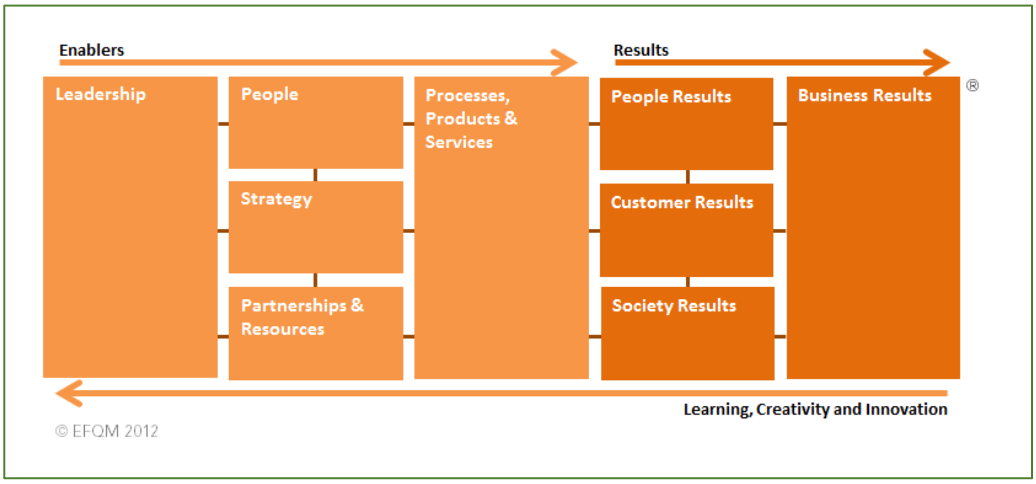

Fig. 4. EFQM Excellence Model. Source: EFQM (2015).

EFQM 2013 states that each of the nine criteria has a definition, which explains the weight and implication of each criterion. Every criterion comprises a number of elements formulated as statements that describe examples of what can typically be seen in excellent organizations and what should be considered part of self-evaluation, which, in its turn, is part of the quality system. The model is based on eight fundamental concepts of excellence (adding value for customers; creating a sustainable future; developing organizational capability; harnessing creativity & innovation; leading with vision, inspiration & integrity; managing with agility; succeeding through the talent of people; sustaining outstanding results). [14]

2. PILOT PROJECT OF INTEGRATION OF THE EFQM CRITERIA WITH KPI

In order to synchronize processes of university strategy development and monitoring and quality system pilot project was launched to combine these platforms. Objectives of process synchronization was to make both platforms more integrated and systemic, that would lead to increased efficiency, reduce duplication of data management and quality indicators play more significant role in determining universities strategy. Method to evaluate process was quantitative and qualitative analysis. As for quantitative analysis surveys were sent out. Qualitative analysis was conducted through individual meetings and interviews. In this article, the authors consider integration of RTU KPI in RTU EFQM quality system model. In case of RTU, all KPI can be classified as EFQM result criteria, see Fig. 4. More than 150 experts and stakeholders participated in the research to evaluate correspondence of each of RTU 32 strategy KPI with the EFQM criteria and corresponding sub-criteria. Afterwards, interviews with some RTU staff members, students, project managers and other stakeholder were carried out. Completing the questionnaires, respondents, based on their opinion, had to evaluate which KPI fits best a with certain EFQM sub-criteria. In some cases, results were equally divided between two or more criteria, then this indicator was represented in more than one slot. Table 1 shows integration of strategy indicators in the EFQM result criteria, more detailed sub-criteria relations were not included in this paper. This analysis was very useful to set a framework for EFQM quality system that later was used to draw up a fact-based self-evaluation report.

Table 1. Integration of RTU Strategy indicators in the EFQM result criteria

No.	Indicator	EFQM Result Criteria			
		Customer Results	People Results	Society Results	Business Results
	Study indicators				
1.	Total number of students	X			X
2.	Number of graduates			X	X
3.	Student drop-out rate	X			
4.	Number of foreign students	X			X
5.	Number of study programs	X			
6.	Average age of academic personnel		X		
7.	Number of study programs in English	X			
8.	Number of study programs implemented jointly with other universities	X			
9.	Number of study subjects implemented in English	X			
10.	Average rate of faculty evaluation done by students	X			
11.	Relative number of academic personnel with Doctor's degree		X		
12.	Number of foreign guest professors		X		
	Scientific research process indicators				
13.	Number of scientific research staff		X		
14.	Number of scientific research staff (FTE)		X		
15.	Average age of research personnel		X		
16.	Relative number of research personnel younger than 35 years		X		
17.	Implemented scientific projects financed by external funding				X
18.	Attracted external research funding ('000 EUR)/ Number of scientific research staff (FTE)		X		
19.	Publications and citations				X
20.	Number of organized seminars and conferences			X

31.	Number of created new spin-offs			X	
32.	Number of created new spin-offs active for at least 2 years			X	

RTU Approach to Pursuing Excellence defines the following steps to achieve sustainable development of RTU: stating and planning required results, Approach, Implementation, Assessment and refinement, as it can be seen in Fig 5.

Fig. 5. Stages of RTU Approach to Pursuing Excellence. Source: RTU Approach to Pursuing Excellence (2017).

Fig. 5 presents the process cycle of ensuring excellence. Initially, RTU Mission, Vision and Values are set by RTU Senate and administration. They are mainly focused on setting achievable goals, developing and reinforcing more competitive national economy through creation of additional value for perspective graduates and existing students. Keeping this in mind, RTU has set its goals that are implemented within RTU Strategy, which focuses on high quality study process, excellence in research and sustainable valorization. Once all strategic objectives are set, action plan is drawn up listing concrete activities how to improve university performance and to help achieve the targets set previously. Implementation phase begins with systematic process oriented review of the real time data. Analyzed data is used to further enhance the process or make conclusions on the set targets. This is conducted by RTU Quality Management Unit. Once a year, the university prepares a self-evaluation report to analyze the processes and consider possible improvements in the future in terms of Action Plan and Strategy implementation process. After self-evaluation and analysis of performance data, proposals for administration to introduce further changes for continuous improvement are made.

3. DEFINING ACTION PLAN PRIORITIES

Creation of the Action Plan means defining clear tasks, and that allows setting detailed key performance indicators, appointing responsible units and setting deadlines. This year, the pilot project dedicated to the introduction of new methodology how to develop an Action Plan at RTU has been launched. Various stakeholders were involved as participants in creating Strategy Action Plan, which is managed by administration of the university. Challenge is to have the mechanism on how to select ideas that should be included in the strategy. In case of RTU, this becomes even more challenging as the current process allows collecting proposals and ideas from a variety of sources. Focus group reviews indicate that more input sources lead to more proposals and pool of action ideas. This makes development of the strategy action plan more effective. It helps to include employees, mid-level managers, and other stakeholders in the decision-making process, increases awareness of the strategy, quality of action plan and helps to implement the strategy in general. Certainly, it is not possible to implement all actions included the Strategy due to numerous reasons but mainly due to lack of resources. Ideas should be prioritized and RTU has created the methodology to do so. In case of RTU, the Action Plan is reviewed annually. Input for the Action Plan is generated from the review of the previous Action Plan results; senior management input; self-evaluation group input; quality management unit input; employee surveys, and the input from internal and external auditors. All Action Plan proposals are evaluated with action coefficient Eq. (1) where based obtained results list is prioritized list is generated. Pool of ideas is rated as shown in Table 2 at strategy review meetings, usually led by Vice-Rector in each of strategy field (Fig.1) with representatives from all faculties and some central units. The bigger A_c, the more actions should be included in the Strategy.

Table 2. Action prioritizing

Action (A_c)	*Importance (I)*	*Urgency (U)*	*Needed resources (R)*	*Impact on strategy implementation (S)*	*Priority group*
1st action	1 to 10	1 to 10	1 to 0,1	1 to 10	1 to …n
2nd action	1 to 10	1 to 10	1 to 0,1	1 to 10	1 to …n
n action	1 to 10	1 to 10	1 to 0,1	1 to 10	1 to …n

The maximum score for A_c is 1,000 if the action has high importance and urgency, it does not require a lot of resources and has significant contribution to implementing the general strategy. After all actions are scored and A_c is calculated according to Eq. (1), results priority group is given as shown in Table 2. It is decided by the senior management on how to prioritize the list.

$$Ac = I * U * R * S \quad (1).$$

This leaves the window for senior management to decide what action should be listed in the lower priority group. The final decision on the priority groups to be included in the Strategy is made by the Rector. Research showed that introducing periodic reviews of the Action Plan has changed organizational culture as more people feel involved. For example, respondents indicated that since their inclusion in the process, they more actively support the overall strategy implementation and that the quality of their work has been influenced.

4. SUMMARY AND CONCLUSIONS

The pilot project to integrate Strategy development with the EFQM system can be considered successful at RTU to combine strategy and quality system platforms. Complete cycle of stating and planning required results, Approach, Implementation, Assessment and refinement has been developed. The research showed which Strategy KPI’s should be included in the EFQM criteria and analyzed in the self-evaluation report. Employees have better understanding of which outcomes of their work are expected and will be evaluated. Overall support to strategy implementation has increased. Action Plan tasks are prioritized by evaluating and scoring their importance, urgency, required resources and impact on strategy implementation. Research findings confirmed that the EFQM Model integration in strategy development has had a positive effect on achieving key performance indicators. More comprehensive action plan development process has been introduced, which is based on input from various stakeholders. Further analysis should be conducted to evaluate the impact of EFQM enabler criteria on KPI. Because of pilot project both platforms of strategy and quality monitoring were combined, making strategy development aligned with quality system and quality system more supporting of strategy KPI. Pilot process showed, that if people working on both processes work together then it leads to increased efficiency and better governance of data. This helps both units to use the date for analysis and better understand each other. This also eliminates waste in working hours as it reduces duplication of data management. Employees connected with both processes confirmed that data analysis is quicker than if both units do it separately. Another conclusion with closer integration is that quality indicators play more significant role on processes to support strategies KPI. This has led to more increased KPI influence on process outcomes.

ABSTRACT

In the Yerevan Communiqué (2015) ministers in charge of higher education in the EHEA promoted the transnational aspects of quality assurance (QA). However, the internationalisation of the QA activities is far from having reached the objectives assigned by the ministers. The main hindrance comes from the national regulations, which do not allow or strongly restrain home institutions to call for accreditation by foreign agencies.

Although experiences of transnational accreditations of programmes are not unusual, and calls to international experts in national accreditation teams tends to be a standard, the delegation to a foreign agency of the quality assessment of the whole national engineering education, is a rather unique experience.

This paper deals with the accreditation of all the Flemish civil engineer's programmes in Belgium by the French agency CTI. It describes shortly the origin and the building of the project, and gives the analyses of the experience from the respective point of views of the accreditors (CTI) and of a senior representative from an accredited institution (KU Leuven).

Conference Key Areas: Quality Assurance and Accreditation, Curriculum Development
Keywords: Cross-border, Internationalisation, Quality Assurance

INTRODUCTION

From the origin of the European Higher Education Area (EHEA), the Conferences of ministers in charge of Higher Education, emphasize the international dimension of QA (Quality Assurance); in the Bucharest communiqué [1], they set as a priority to "allow (..) registered quality assurance agencies to perform their activities across EHEA, while complying with national requirements".
Despite the noted advances of the Bologna process, the internationalisation of the QA activities is far from having reached the objectives assigned by the ministers. The main hindrance comes from the national regulations, which -apart in some countries as for example Germany or Switzerland- do not allow or strongly restrain home institutions to call for accreditation by foreign agencies. To this must be added the language barrier and the widespread feeling that the foreign experts team may not perceive and understand the national specificities.

If experiences of transnational accreditations are reported, very few deal with a complete field of higher education. This paper deals with the accreditation of all the Flemish civil engineering programmes in Belgium by the French CTI agency, which is a rather unique experience as quality assessment of a whole national field of education, delegated to a foreign agency. It will be described in the following sections; respectively, the origin and the building of the project (sect. 1); the analysis of the experience from the accreditors (CTI) point of view (sect. 2), and the view from a senior representative of an accredited institution (KU Leuven) (sect. 3).

1 THE ORIGIN AND THE BUILDING OF THE PROJECT

1.1 The "Commission des Titres d'ingénieur" (CTI)

In France, the "Commission des titres d'ingénieur" (CTI) is an accreditation body established 80 years ago (1934) by the French law, responsible for setting the standards for the "titre d'ingénieur diplômé" (master degree of engineering science) and for the programme accreditation in higher education institutions willing to deliver it. CTI is an autonomous institution equally composed on the one hand of representatives of employers and professional engineers, and on the other hand of academia [2]. CTI contributed to the Bologna process in the French engineering domain; it is member of ENQA (European Network for Quality Assurance), registered in EQAR (European Quality Assurance Register) and a founding member of ENAEE (European Network for Accreditation of the Engineering Education).

In addition to its national QA activities (more than 200 Higher Education Institutions delivering engineering degrees to about 35 000 graduates per year), CTI has set standards and procedures for transnational accreditation [3] and has a well-established international experience (about 130 programmes accredited in Belgium, Bulgaria, Burkina Faso, China, Switzerland, Viet Nam; others in process in Tunisia, Morocco, etc.). Transnational accreditation is part of CTI's mission from its beginning; its founding law states that the graduates of foreign accredited programmes are entitled

to hold the" titre d'ingénieur diplômé" and have the same professional recognition in France as graduates of national institutions (procedure of "Admission par l'Etat").
CTI is authorized by ENAEE [4] to award the EUR-ACE® label to the programmes which fulfil the Framework Standards and Guidelines (EAFSG) [5].

1.2 The three Flemish Universities and the national context

The three Flemish civil engineer's programmes involved in the procedure described in this paper are organized by the Vrije Universiteit Brussel (Brussels), KU Leuven University (Leuven) and Ghent University (Ghent).
Since the 1990's, visitations (and later accreditations) of higher education institutions are mandatory in Flanders. This is organized, together with The Netherlands by the NVAO (Nederlands-Vlaamse Acreditatie Organisatie). Visitations were planned by programme, and took place every 8 years. Nearly every year some programmes were visited. For the universities, this was a large burden. A long, separate Self Evaluation Report had to be written for every visitation. The commissions that came for the visitations, often had several non-engineer members, giving sometimes rise to comments that were not perceived by the faculties and their teaching staff as to the point, but rather out of scope.
Replacing this system by a visitation by CTI was a great opportunity for several reasons. First, it is an accreditation by engineers. The supposition was that the comments would be more tailored towards the engineering field. Second, CTI looks at the 5-year programme (3 years of Bachelor, and 2 years of Master) as a whole. As the specific competences that are crucial for an engineer are introduced in the Bachelor, and further developed in the Master programmes, only accrediting the Bachelor, or only accrediting the Master, makes less sense. Third, the CTI approach visits the whole faculty in one movement. This allowed all programmes of each faculty to join forces in quality assurance. It was an opportunity to sharpen their vision and objectives, and to write texts at the level of the Faculty, which was not done before in a systematic way. Last but not least, the texts required by CTI were perceived as much more to the point than the texts that used to be asked by the NVAO. They were less extensive, much more focused. A 50-page Self Evaluation Report had to be written for the faculty and each programme had to write a specific report of 4 pages. This allowed the faculty to concentrate on the essentials.

1.3 The project building

The first contacts with CTI were informally taken in 2010 and then at the SEFI conference in Leuven in 2013. Under the aegis of the Flemish Interuniversity Council (VLIR), CTI and the Flemish faculties set a procedure, based on agreed Terms of Reference (TOR, January 2014).
Before the starting of the accreditation procedures, a change occurred in the legal context. On June 2015, the Flemish Parliament approved a revision to the system of quality assurance and accreditation in higher education, with an evolution towards full institutional accreditation in 2020 and a suspension of the previous programme accreditation system. Consequently, NVAO and VLIR were released from their commitments in the agreed process.
However, even though they were no longer legally required to do so, the three faculties decided to go on and to ask CTI alone the accreditation of their engineering programmes. A latest version of the Terms of Reference (TOR September 2015) was worked out, where the three faculties "seek accreditation by CTI through the procedure of "admission par l'Etat" with the possibility to "request the EUR-ACE label".
The degree programmes concerned by the assessment process comprise:

- Bachelor programmes (180 ECTS): Bachelor of Engineering and Bachelor of Engineering Architecture. These programmes have no professional objectives, almost all their graduates immediately enter a master degree programme in line with the options they selected during their Bachelor studies; as such these programmes are neither eligible for the procedure of “admission par l’Etat”, nor for the EUR-ACE label; however, their quality was assessed and a review report published with recommendations.
- Master programmes (120 ECTS): most of these programmes are taught in English; to be compliant with the Flemish regulation they are also offered in Dutch; as the two tracks share the same learning outcomes, they were considered as a single degree programme. When Master degree programmes were jointly prepared by two (Flemish) universities, one faculty was selected to present the application on behalf of the two. Some Masters programmes presented by Vrije Universiteit Brussel (VUB) are joint programmes with the French-speaking “Université Libre de Bruxelles” (BRUFACE project). All these Master programmes are eligible for “Admission par l’Etat” and for the EUR-ACE label.

At least, the Flemish faculties were successful in their application to the European project Erasmus; consequently, several master programmes asking for accreditation are prepared by a consortium of European universities; they were presented by the Flemish university of the consortium, although it was not always clear that all the members were equally informed of the accreditation process and that they equally share the same learning objectives.

2 THE ACCREDITOR’S VIEW

Beyond the needs of human resources and the organisation constraints, the accreditation campaign was a very rich and demanding experience for CTI and for the persons who contributed to it.

The objective of this section is not to present a comprehensive report on the accreditation results (which are available on the CTI website [6]), but to present the insights which can be extracted from such an experience and to contribute to the enhancement of international collaborations in Quality Assurance [7].

2.1 The favourable key factors

The accreditation campaign was not the result from a top-down decision of the University directions or from legal requirements, but from a collective initiative of the deans and of the programme managers. This has resulted in a remarkable implication of all faculty staffs, an outstanding quality of the self-evaluation reports and a very active participation to all the audit meetings. The operations -notwithstanding their complexity- were made easier too by the culture of Quality Assurance obviously implemented in the faculties and shared by the academic and administrative staff, which does not imply a total agreement on the objectives of the process (see below).

The three universities involved have clearly their own personality owing to their history and cultural backgrounds; however, the engineering studies are regulated at the national level by stringent regulations – sometimes considered by the experts as too stringent-; this homogeneity saved experts’ time and efforts, as they could rapidly focus on each faculty specificities.

2.2 Specific issues

CTI national language is French, Dutch is the national language of the Flanders; it was decided that the working language would be English and that the main documents, including the self-evaluation report (SER), must be written in English. Most masters

are taught in English and the Flemish students and teachers speak fluent English; however, a very sizeable amount of student works and of teaching documents were written in Dutch; the participation of Dutch speaking experts was very helpful although the scientific contents of the documents allowed the experts to grab their topic and level. Besides the need to translate from Dutch to English some key documents and to translate to French the experts' report for the CTI plenary session, the language issues have not raised important difficulties.
The three universities are research-driven and roughly built on the so-called "von Humboldt" model with a strong emphasis on the scientific excellence and on the academic freedom of professors in their research and lectures [8]; this feature clearly favours the individual initiatives and the bottom-up approach to the collective decisions; it may however contradict with the Quality Assurance culture in general which assigns collective objectives and collective assessment methods.
At several occasions, such ongoing misalignments showed up in the interviews or in the documents when individuals or teams seemed reluctant to apply the policy globally approved at the faculty or at the university levels.

In Flanders, the employment of the civil engineers is very good, with a high demand for graduates. The employers report their difficulties to hire skilled employees in this domain. Clearly the less than 1 000 civil engineers graduating per year in Flanders are far from fulfilling the national (and international) job market needs, taking also into account that many engage in Doctorate studies. This excellent employment situation does not induce the engineering faculties to develop the employability of their graduates; the experts regretted the lack of statistics on the engineers' job market, the average time for job search for each programme, the professional trajectories of the graduates, etc., that one expects from pre-professional curricula.

2.3 The case of the "international" curricula

A difficulty arose for the "international" curricula and especially the Erasmus Mundus programmes (or their successors when the Erasmus contract is ended). They are high level and highly selective programmes, the scientific quality of which is not arguable. However, engineering programmes -particularly according to the CTI and ENAEE's criteria- are pre-professional degrees, the accreditation of which must guarantee that every graduate acquired the skills and competences expected from an engineer and specified in the outcome profile published by the faculty.
In the pool of universities which support the transnational degree, it was sometimes difficult to assess that all partners are aware of and that all implement at the same level the pedagogical objectives and methods, which are subject to assessment in the visited university (here Flemish). There were sometimes evidences of the contrary: the curriculum which is designed in Flanders as an engineer degree with all its all-about, is presented as a pure research degree in a partner university. Furthermore, owing to the Erasmus rules, students may obtain the degree from a university where they spent a small part (if not no part at all) of their studies; if this is not arguable from a purely academic point of view, it raises very important issues for the entry into the profession and for the relation with the employers.

3 THE VIEW OF THE LEUVEN FACULTY

KU Leuven is a comprehensive university, with over 55.000 students. It is a typical research-oriented university, member of LERU (League of European Research Universities). It is well ranked internationally, especially for innovation.
The Faculty of Engineering Science (FES) counts over 3.500 students. It offers 2 Bachelor's programmes (a general Bachelor of Engineering, and a Bachelor of

Engineering: Architecture), 12 Master programmes and 6 advanced Master programmes. In the departments over the FES, more than 1.000 PhD students are doing research. The largest part of research funding is acquired through competitive calls.

3.1 Approach taken

Quality assurance is the task of all people involved in education. The FES has a small support team that gives assistance for quality assurance where needed in the Faculty. This team was strengthened by one extra person for 2.5 years.

First, for each of the Bachelor's and Master's programmes, a detailed set of learning outcomes was identified and formulated in the ACQA framework (Academic Competences and Quality Assurance [9]). This was followed by a comprehensive curriculum mapping, linking courses to outcomes. This effort has led to valuable insights into the structure, strengths and weaknesses of each programme.

Second, all course descriptions (so called ECTS files in Leuven) were revisited. Special attention was given to the correct formulation of the goals of each course, and of a detailed description of evaluation criteria and organization.

Third, several questionnaires were launched. One aiming students finishing their degree. The questions pertained the whole of the curriculum, and covered all classical areas of quality assurance. The answers complemented the regular questionnaires organized by the university for each course at least every 3 years. A different questionnaire was sent to the alumni of the faculty, focusing on the more recent alumni of the last 5 years.

Fourth, several industrial advisory boards (IAB) were installed as not every programme had the tradition of meeting regularly with representatives of industry.

The curriculum mappings, the output of the questionnaires, and the comments of the IABs, were used to discuss in length, both at the level of the faculty as at the level of each individual programme, an extensive SWOT analysis. These SWOT analyses resulted in actions plans, again both at the level of the faculty as at the level of each programme.

The writing of the faculty SER was started about 18 months before the deadline. The good table of contents of CTI allowed the FES to describe its vision, strategy and processes in a structured and comprehensive manner. The SER was complemented with several annexes, giving more details about topics such as programme outcomes and the extensive problem solving and design pathway. The SER of the faculty was extensively discussed at all levels of the faculty (including the students) and with the Senate (specifically the vision and strategy aspects).

3.2 Research-oriented nature of the KU Leuven

The fact that the KU Leuven is a typical research-oriented university has its influence on several aspects. First, the education is given by top researchers in their field. The students are involved in the research (through several projects and their master thesis), and special attention is given to research skills. As professors are keen on hiring top PhD students, they pay a lot of attention to education. Furthermore, often the top researchers are also the best lecturers! Researchers have an innovation mindset, and are ready to innovate in their education – as long as the university and faculty do not ask to change everything every 6 months!

However, education is not always the main focus of top researchers. They often are more concerned with their own contributions to the programme (contributions that are focused on their research), than with the programme as a whole. This led CTI to qualify the programs as content-driven, and less as output-driven.

3.3 Outcome of CTI for KU Leuven

The exercise of self-evaluation, and all the activities described above to prepare the visitation by CTI boosted the quality assurance mind set, and gave rise to a global enthusiasm towards quality of education, and this both at the faculty level as at the level of each individual programme. The texts that were produced were written in a way that they could be re-used on websites, in brochures, in university-wide actions.
The visitation itself, and the report by CTI, although interesting, brought less new insights. At the level of the faculty there was a short but sharp analysis. The strong points included the first rated scientific environment, the research-driven focus and the high level of acquired scientific competences by the students, initiatives such as ACQA [9] and the programme solving pathway, and the quality of the provided documents. Some of the weak points are a result of the research-driven focus, such as lacking a comprehensive view and proper management of non-scientific learning outcomes, and the reluctance to some extent of involving all external stakeholders in the formal supervision of programme content and outcomes.
The level of feedback for each individual programme varied strongly. The feedback was never extensive.
It is clear that the main benefit of the whole process lies in the strong groundwork that was done. The preparation and the writing of the SER gave the faculty and its programmes a mirror. The process of CTI, including the table of contents of the SER, guided this reflection. For the faculty, this was a strong momentum.

3.4 The future

The legal landscape in Flanders has changed. In the meantime, visitations and accreditations of individual programmes have been put on hold by the Flemish government. A system of institutional reviews has been set up, where each institution for higher education in Flanders is visited as a whole, including its quality assurance system.
The new quality assurance system of the KU Leuven, called COBRA, is based on regular reflection meetings of primary actors (students, lecturers, other education staff). The problems that come up in these reflection meetings are either solved locally or are pushed to a higher level (first faculty level, than university level). Each 4 years external peers, the working environment and alumni are involved in the reflection.
The FES, as a faculty of the KU Leuven, will implement the COBRA system. The question is if they will continue the accreditation process with CTI. Having to conform to two separate systems of quality assurance is of course extra work. The EUR-ACE label that can be acquired through CTI is certainly an incentive for continuing with CTI.

4 CONCLUDING REMARKS

This paper addresses most questions raised in the report on “cross-border quality assurance” [7] published by EQAR and the E4 group. It draws up the benefits and problems for both the agency and the institution points of view.
The main difficulty concerned the “international” curricula (i.e. supported by a pool of international universities); they enter in the category of “joint degrees” which are strongly promoted within the EHEA. Specific guiding principles [7] were not anticipated and then not met during the process, e.g. a) “the external quality assurance procedure should be based on a SER jointly submitted by the cooperating institutions, or b) the site visit should therefore include discussions with representatives of all cooperating institutions. For these programmes, notwithstanding their scientific excellence, the assessment could not be conclusive.

There is a strong ongoing debate on the pros and cons of programme accreditation vs. institutional accreditation; the programme accreditation performed by CTI in Flanders comprises an important institutional component, since all the degrees of each faculty were concerned in a single round.
Such a procedure is more efficient and allows to involve all the faculty staff for a self-assessment. However, as one can only expect to have one or two experts per domain, each professor has less chance to discuss in detail his/her teachings with a peer colleague; some may feel some frustration when they are eager to demonstrate the high scientific level of their teachings.
But the assessment could focus more on the general objectives and outcomes, and on the quality of pedagogical processes; more time was dedicated to the interviews of the governing bodies of the faculties and to the stakeholders (as the employers and alumni). A whole faculty assessment is then more coherent with the quality assurance fundaments which aim to assess the quality of the internal processes and not to certify the detailed contents of the curricula [10].

ABSTRACT

In recent years, China’s engineering education has trained a large number of qualified talents for the development of China's economy and society, and has made due contributions to the global economy. Based on a brief introduction of the current development situation of China's engineering education, this research, firstly, systematically reviews the development process of China's engineering education accreditation system (CEEAS) from its start in 1992 to 2016; secondly, focuses on analysing institutional framework, accreditation standard and accreditation procedure of CEEAS; thirdly, emphasizes comparing the differences of engineering education accreditation system between China and the main contracting countries of the Washington Accord in order to analyse the existing problems of CEEAS; finally, reflects the problems existing in the construction of CEEAS.

Conference Key Areas: Quality Assurance and Accreditation; Sustainability and Engineering Education; Engineering Education Research

Keywords: Engineering education; Accreditation system; System construction; International mutual recognition; Washington Accord

INTRODUCTION

Since the founding of the People’s Republic of China in 1949, engineering education has trained more than 20,000,000 engineering talents for China's industrialization and social economic development. As of 2015, 1,650 colleges and universities have

[1] Corresponding Author:
Dexin Hu
hdx15@mails.tsinghua.edu.cn

set up engineering specialties, and the number of specialties reaches to 16,284. Engineering undergraduates have up to 5,247,000, accounting for about 33.3% of the total number of students at school. The rapid development of industrialization determines that China has a strong demand for engineering talents, and the number of graduates in colleges and universities in China is rapidly increasing. In terms of scale, China has a huge number of students in engineering education and has ranked the first in the world.

With the rapid expansion of scale and the higher standard of training quality of engineering talents, the existing engineering education quality assurance system is facing a severe test. On the other hand, with the development of economic globalization, the internationalization trend of engineering education is becoming clearer, and the transnational flow of engineering talents is also becoming more frequent. In this process, the educational and industrial sectors in China have recognized that it is necessary to establish China's engineering education accreditation system (CEEAS) with international substantial equivalence.

1 REVIEWING DEVELOPMENT HISTORY OF CEEAS

CEEAS launched a pilot project of the architectural accreditation in 1992, which has 15 years' development history. The former Ministry of Construction started a pilot scheme of 6 majors' accreditation in Tsinghua University, Tongji University, Tianjin University and Southeast University from 1992, and began to explore the practice of CEEAS(Fang 2013)..

In 2005, the State Council approved the establishment of the China Engineers System Reform and Coordination Group (CESRCG). The Ministry of Human Resources and Social Security is the head of the unit, and Chinese Academy of Engineering, Chinese Association for Science and Technology (CAST), the Ministry of Education is the deputy head of the unit. Three deputy heads of the unit are respectively responsible for the classification and design of the engineers system, external contact of accreditation and engineers, engineering education accreditation.

In 2007, after the approval of CESRCG, the Ministry of Education set up Experts Committee of China Engineering Education Accreditation (ECCEEA). With referring to the current international and domestic practice, ECCEEA formulated a set of guidance documents for CEEAS, including accreditation standard, accreditation procedure, accreditation policy etc. The ECCEEA worked until December 31, 2011, and the newly established China Engineering Education Accreditation Association (CEEAA) took over the accreditation work in 2012. In October 2015, CEEAA formally established, which was a national, non-profit, membership-based organization organized by more than 30 organizations and individuals. Under the leadership of the CAST, it is the only legal institution authorized by the Ministry of Education to carry out engineering education accreditation in China.

At the end of January 2013, China was accepted as a probationary member of the Washington Accord. In June 2016, China became the eighteenth formal member of the Washington Accord, which indicated that the quality standard of China's engineering education has basically achieved the international substantive equivalence and has been gradually recognized by international community.

2 THE CONSTRUCTION OF CEEAS

2.1 Institutional framework

CEEAA is responsible for the organization, implementation and management of China's engineering education accreditation. The association currently has 33 group members and some individual members. The group members cover the major trade and professional associations in engineering fields, and the individual members include the leaders and experts from government, universities, industry organizations and enterprises.

There is board of supervisors, council and secretariat under CEEAA. The council is the executive body of the association. The board of supervisors is responsible for overseeing the work of the council and the secretariat. The council includes Specialty Accreditation Committee (SAC), the Accreditation Conclusion and Review Committee (ACRC) and the Academic Committee (AC) (Figure 1). The SAC is the branch of CEEAA, which is established in accordance with the relevant professional fields.As of 2016, CEEAA has a total of 14 SAC, including mechanical, computer, chemical and pharmaceutical etc. The AC is responsible for formulating and revising accreditation standard and other accreditation documents, providing academic support for engineering education accreditation, and accrediting qualification for experts. The ACRC is responsible for considering accreditation report and accreditation conclusion made by the SAC and submitting the results to the council for approval.

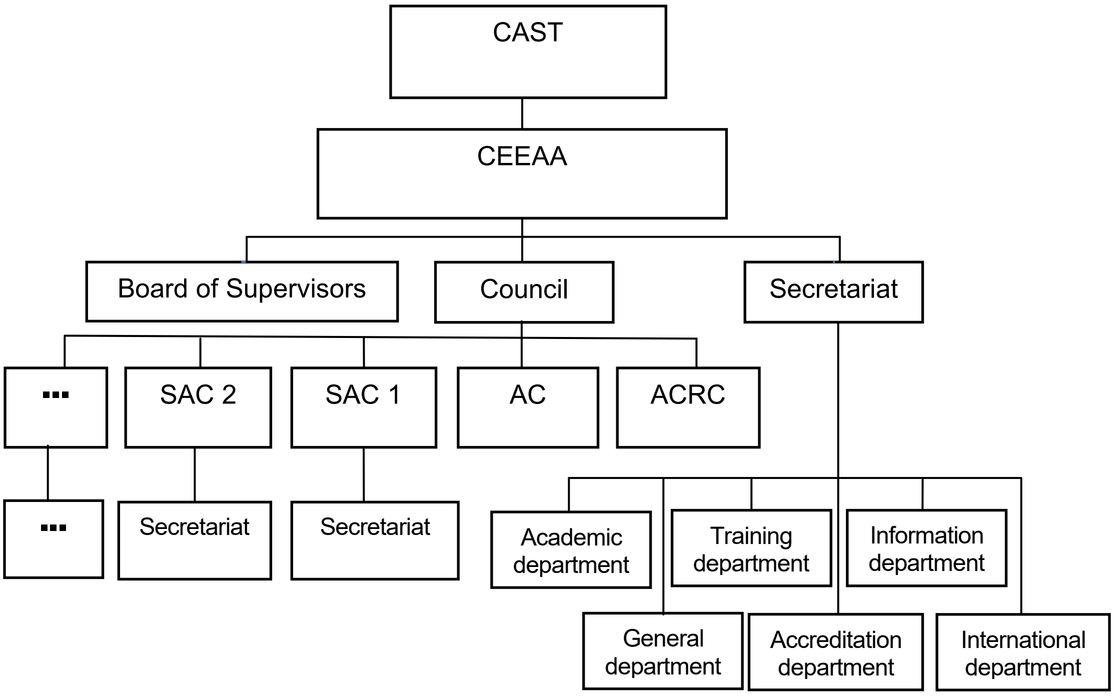

Fig. 1. The framework of CEEAA

2.2 Accreditation standard

The accreditation standard is composed of two parts: general standard and supplementary standard. The general standard is consisted of seven elements: student, training objective, graduation requirements, continuous improvement, curriculum system, teachers and support condition. The supplementary standard specifies the special professional requirements and supplements of one or more areas (Table 1).It needs to be emphasized that: (1) The certification standard only contains 7 indicators, and 21 investigation points are just as the reference; (2) The supplementary standard is not a single index, but the content supplement that is not included in the general standard; (3) The training objective covers internationally accepted 11 capability requirements of graduates and accords with result-oriented characteristic of the Washington Accord (ABET 2007).

Table 1. Accreditation standard and connotation interpretation

Type	Index	Investigation point
General standard	Training objective	Target evaluation and revision
		Graduate ability
	Curriculum system	Curriculum
		Practice link
		Thesis
	Teachers	Number and structure of teachers
		Teacher development
	Support condition	Teaching funds
		teaching facilities
		Teaching management and service
		Books
		Industry-university-research cooperation
	Students	Recruit students
		Student training and guidance
		Student employment
	Continuous improvement	Quality control of teaching process
		Graduates feedback
	Graduation requirements	Theoretical knowledge
		practical ability
		Professional ethics
		Lifelong learning
Supplementary standard	Special requirements for each specialty	

2.3 Accreditation procedure

The process of accreditation is basically the same as that of most members of the Washington Accord, including 6 links: application and acceptance, school self-assessment, review of self-assessment report, on-the-spot investigation, accreditation conclusion, accreditation status’s maintenance and improvement. Therefore, this study will no longer carry out specific discourse.

3 COMPARISON THE DIFFERENCES OF ACCREDITATION SYSTEMS

The core content of the Washington Accord is that the accreditation standard and procedure of each member are basically the same (Patil & Codner 2007). In order to achieve the objectives of the agreement, the institutional framework, accreditation standard and accreditation procedure developed by each member have shown great similarities. However, viewing the current practice, there are many differences between China and the main contracting countries of the Washington Accord. This study mainly analyses the differences from the cognition level, organization level, system level and practice level.

3.1 Cognition level

In the construction of engineering education accreditation system, the government, universities, industry and professional associations in the most contracting countries of the Washington Accord have a high degree of acceptance. Taking the design of accreditation standard as an example, Accreditation Board for Engineering and Technology of the United States (ABET) adopted the Engineering Criterion 2000 (EC 2000) in 1997, which realized the innovation of quality evaluation standard. In the design process of EC2000, the government, universities, industry and professional associations participate actively and play different functions. In the premise of full participation by all parties, accreditation system has a high acceptance and authority.

The design concept of CEEAS draws lessons from EC2000 and has maintained a high consistency with the Washington Accord (Han & Zhang 2015). However, the design of CEEAS is dominated by the government and the universities, and the industrial sectors are not effectively involved. Secondly, the phenomenon that emphasizes on the theoretical education and neglects the practical education in the process of students training in universities still exists, which leads that students' engineering practice ability is still not strong enough. The training of engineering talents in universities cannot fully meet the requirements of the industrial sectors (Zhu 2015), indirectly causing that the enthusiasm of the industry to participate in accreditation is not high. Overall, the acceptance of industrial sectors to CEEAS needs to be improved.

3.2 Organization level

Accreditation institutions in various countries have different development history, and the form is also unique. However, the development of accreditation institutions is closely linked with the social and economic development at that time. At the end of 1980s, with the needs to guarantee the quality of engineering education and the acceleration of economic globalization, accreditation has become an important function of engineering education organizations in various countries, and the emergence of international mutual recognition agreement on engineering education has also become inevitable. The Washington Accord was born under such a background.

Accreditation organizations of the main contracting countries of the Washington Accord are generally unofficial and independent institutions. For example, the ABET, established in 1932, is a non-governmental organization. As an organization of membership, ABET has a sound management mechanism and organizational structure with a high degree of independence and professionalism, and the authority of it is admitted by both the official and unofficial (Bi 2005). In contrast, China's accreditation organization has a big difference with ABET. The government plays a leading role in current accreditation organization, and it is involved in the work of the accreditation organization with the direct administrative means. Although the establishment of CEEAA promotes the independence and professionalism of accreditation organization, the official dominant colour still exists.

3.3 System level

The ultimate goal of the Washington Accord is to ensure that the graduates has professional qualifications in the field of their work after a certain period of time and continues to maintain and improve their vocational ability. Therefore, the effective convergence of accreditation system and engineer accreditation registration system is very important. At present, the accreditation institutions of the Washington Accord (such as Australia, Canada, Hong Kong, Ireland, New Zealand, Singapore, South Africa, Britain, Malaysia, Sri Lanka etc.) are comprehensive accreditation agencies, which are not only responsible for the accreditation of engineering education degree, but also the professional qualifications of engineers.

At present, excepting architecture or related majors, CEEAS is in a relatively isolated position, and failed to achieve effective convergence with engineer registration system. According to a survey, the enthusiasm of schools and students for accreditation begins to decrease, and many students think that their employment does not matter much with accreditation system. In addition, the industry is not very concerned about whether the school's specialty has passed the accreditation or not in the recruitment. This is largely due to lacking of effective convergence between accreditation system and engineer registration system.

3.4 Practice level

Compared with the main contracting countries of the Washington Accord, China has a large number of specialties that need to be certified and the scale of accreditation is growing too fast. Since 2006, the scale of China's accreditation has increased year by year, from 8 specialties in 2006 to 375 specialties in 2016, with an average annual growth rate of 46.9% (Figure 2). As of the end of 2016, China has certified 996 specialties, accounting for 6.1% of the total. Therefore, the future workload of accreditation is very large, which needs a huge and experienced team of experts.

Most members of the Washington Accord have a wealth of practical experience, encompassing a large number of experts with reasonable structure and high quality. Viewing the current practice, there are many problems in the quantity, structure and quality of China's accreditation team. At present, China's accreditation team only has about 600 people, which causing it is difficult to guarantee the accreditation quality in such a large workload. At the same time, the experts are mainly from the university's teachers and administrative staffs. They generally become a probationary expert through a simple training and become a formal expert through participation in an accreditation work. Therefore, a considerable number of experts lack accreditation experience and cannot have a good grasp of the concept, principle and standard of accreditation.

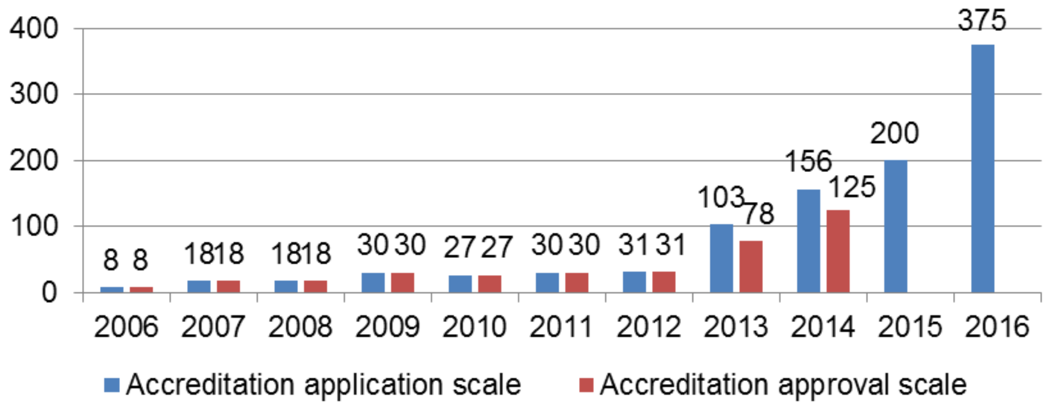

Fig. 2. Accreditation application scale and approval scale

4 REFLECTING THE PROBLEMS EXISTING IN CEEAS

4.1 Enhancing the acceptance of the industry

In the main contracting countries of the Washington Accord, the industry is actively involved in all aspects of accreditation and has a high degree of acceptance to its accreditation system. Therefore, China should strive to strengthen the contact with the industry and promote the industry to participate in the whole process of the CEEAS in order to effectively enhance the acceptance of the industry. Viewing the construction of accreditation bodies, China must formulate detailed working rules as soon as possible in order to clearly define the functions of the industry and gradually form a sound internal operational mechanism of the association. Viewing the improvement of accreditation standard and practice, China should let engineers that have rich practical experience in industry fully participate in the accreditation work, and listen to their opinions and views, so as to enhance the industry acceptance to accreditation conclusion and even the whole accreditation system.

4.2 Building the completely independent and fair accreditation body

The prerequisite for the effective implementation of the accreditation system is the establishment of a fair, professional and standardized accreditation body. The organization responsible for accreditation is generally unofficial institution, such as the America’s ABET, the United Kingdom’s ECUK (Engineering Council UK), and the Japan’s JABEE (Japan Accreditation Board for Engineering Education) etc. At present, CEEAS is still at the preliminary stage of practice and engineering education in China is very large and complex. If China completely imitates the western countries to use unofficial institutions for accreditation, it may not be able to ensure the effective management of accreditation and organizational work. In consideration of China's specific national conditions, China will gradually transform into a fully independent, fair accreditation body in a more mature stage. At the same time, in the process of constructing accreditation body, it is necessary to strengthen the mutual cooperation and make clear the division of functions among the government, universities and the industry, so as to improve the efficiency and quality of the accreditation work.

4.3 Promoting effective convergence between accreditation system and engineer registration system

Accreditation system and engineer registration system are interconnected and interactive. The main contracting countries of the Washington Accord have different practices in the implementation of the two jobs, but most of them have had a mature experience. Therefore, it is necessary for us to make further analysis and research on their experience, so as to provide reference for the reform of China's accreditation system and engineer registration system. From the view of future, Chinese effective way may be divided into two points. Firstly, China should set up the classification standard of engineering education and the qualification standard for engineers recognized by both the education and industry, in order to lay a good foundation for effective convergence between accreditation system and engineer registration system. Secondly, China should integrate the accreditation bodies and the engineer registration agencies into a system in order to simplify the organization, reduce operating costs, and effectively improve their work efficiency.

4.4 Building a large number of experts with reasonable structure and high quality

The effective implementation of accreditation work requires a high level of experts as a backup. In terms of the quantity, there are only about 600 people engaging in accreditation work in China. With respect to more than 16,000 specialties needed to be certified, the number of experts seems very lack. Therefore, it is necessary to appropriately increase the number of experts to meet the growing demand for accreditation. In terms of the structure, China's accreditation team is mainly composed by experts from universities. For example, when CEEAA organizes a field investigation, the experts group generally has 5 people, but only 1 people are from the industry. Therefore, China should improve the proportion of experts from the industry in order to truly evaluate the quality of engineering education from the perspective of users. In terms of the quality, China should strengthen the training of experts in the accreditation concept, standard and procedure etc. At the same time, it is necessary to strengthen the professional ethics training of experts, so as to improve the impartiality of accreditation.

5 CONCLUSION

After 15 years of development, CEEAS has established a sound accreditation body, accreditation standard and accreditation procedure under the guidance of the Washington Agreement. However compared with the major signatory countries of the Washington Agreement, CEEAS still have some problems and challenges at the cognition level, organization level, system level and practice level. Therefore in the future development of CEEAS, it is necessary to strengthen ties with the industrial sectors and strive to enhance the acceptance of the industry; reduce the direct intervention of government and gradually build a completely independent, fair accreditation body; promote effective convergence between accreditation system and engineer registration system; build a large number of experts with reasonable structure and high quality etc. At the same time, for the actual development of China's engineering education, the number of universities is large, the level of running school is not uniform, and the demand for engineering talents from industries is also different. Therefore, under the premise of maintaining the certification standards and quality standards required by the Washington Agreement, it is necessary for us to think deeply and continue to practice how to maintain the local characteristics of CEEAS.

ABSTRACT

Using a revised Qualification Framework (QF) with four main categories: *-to know*, *- to be*, *-to interact*, and *–to do*, this paper demonstrates how to use the elements of the QF to construct Programme-Qualification Matrices. A general Programme-Qualification Matrix defines the qualifications and their respective conceptual understanding common to all engineering programmes. This is complemented by programme-specific qualification matrices with added emphasis on content and context. Redesigned educational outcomes for three bachelor programmes are presented to demonstrate the versatility of the concept.

Conference Key Areas: Curriculum development, Quality Assurance and Accreditation, Engineering Skills

Keywords: Programme-qualification matrix, educational outcomes, constructive alignment

INTRODUCTION

In a companion paper [1], revisions to the Danish National Qualification Framework (NQF) were proposed in order to facilitate more detailed design and evaluation of engineering programmes at the Technical University of Denmark (DTU). The organization of the proposed qualification framework is repeated here for the reader's convenience.

Table 1. Components of a revised qualification framework [1]

1st level	2nd level descriptors	Description
1: - To know	Knowledge of theories	Acquire and apply terminology and facts, theories, laws of nature, methods, and procedures.
	Knowledge of praxis	Apply knowledge about praxis-induced boundary conditions and their influence on the applicability of theories and methods.
2: - To be	Mind-set	Develop a personal and professional mind-set.
	Self-instruction	Identify need for new knowledge, gather resources, execute, and evaluate learning outcomes.
3: - To interact	Teamwork	Conduct, coordinate, lead, monitor, and develop teamwork.
	Communication	Master language and tools, structure content, choose between narrative styles, edit for logic and clarity, and define communication objectives and receiver competencies.
4: - To do	Operative skills	Advance degree of training, from novice to expert, in executing manual and cognitive tasks.
	Problem solving	Interpret problem information, identify objective, diagnose problem, choose strategy, execute and evaluate solution, interpret impact of solution.

In this paper, the revised framework is used to define educational outcomes for three programmes in B.Sc. in Engineering.

1 PROGRAMME QUALIFACTION MATRICES

1.1 Common qualification elements

The proposed Qualification Framework for programmes at the Bachelor of Science (B. Sc.) level can be divided into elements common to all programmes and elements that are specific to the individual programmes. In this section, the common elements are presented in a *Programme-Qualification Matrix* with Programme-Outcomes listed along the vertical axis and Course levels listed along the horizontal axis.

Table 2 describes the elements of the qualification framework, which are common to all engineering programmes. Levels of *process and element complexity* are indicated by italicised keywords defined in a companion paper [1]. In the four columns to the right, course numbers are to be entered, ordered from left to right by a ranking of object/subject complexity [1]. Multiple course numbers can be entered into each cell. Here fictive course numbers have been used. *Generic foundation* courses (Gen.) are 100-level (courses with no prerequisites), *Discipline core* courses (Cor.) are 200-level (first-level engineering courses) and *Discipline specialization* courses (Spe.) are 300-level (second-level engineering courses). *Capstone* courses (Cap.) relate here to project courses, hands-on courses, internships, and thesis work. Learning activities in the *Capstone* category are annotated in the rightmost column using the following abbreviations: First semester project (1SP), fourth semester project (4SP), hands-on course (HO), B. Sc. Project (BSc).

Table 2. Programme-Qualification Matrix. Common elements. Fictive course numbers

		Object complexity→			
	-To know	Gen.	Cor.	Spe.	Cap.
XXX.K1	**Knowledge of natural science:** Can *classify*, *explain,* and *interpret* facts, terminology, principles, generalisations, theories, models, methods, and procedures within mathematics, physics, chemistry, statistics, and biology, and can *apply* this knowledge to *analyse, evaluate,* and *solve* technical problems.	101 102 103 104 105	201 202 203		1SP 4SP
XXX.K2	**Knowledge of information technology:** Can *use* a programming language and independently *design*, *implement*, test, and document software for technical problem solving. Can, in addition, *explain theories and algorithms underlying* general and specialised software for data acquisition, visualisation, analysis, design, and simulation.	106			1SP 4SP
XXX.K3	**Knowledge of science:** Can *understand* and *assess* the relationship between scientific knowledge and practical experience in creating new technologies, types of knowledge and competences, building the foundation of engineering and the work involved in technological solutions, and the qualities of technologies, and its historic dependency and importance in the development of society.			307	4SP BSc
	-To be				
XXX.B1	**Personal and professional mind-set:** Embodies *self-efficacy*, positive *social attitude,* and *self-governance*. Is *process-oriented* with a hypothesis- and need-driven curiosity, and evidence-based creativity. Thinks logically and critically. Actualize *product-oriented* entrepreneurship founded on safety, reliability, sustainability, usability, serviceability, aesthetics, and ethics.	111 121	211 221 241	321	1SP 4SP BSc
XXX.B2	**Self-instruction:** Is *self-reflective*, *need-aware*, and *metacognitive.* Can orchestrate resources, execute and evaluate learning. Is familiar with and can sort critically between sources of information within the discipline.	121	221 251	321	4SP BSc
	-To interact				
XXX.I1	**Communication:** Master oral and written *language and communication tools* expertly, *structure content* to norms, perform *editorial editing*, can use a variety of *narrative styles* in accord with the standards of the context. Can, through *context analysis*, define the objective of the communication and take into account the competencies of the receiver.	111 121	211 241	321	1SP 4SP BSc
XXX.I2	**Team work:** Can *execute tasks* in teams while observing codes of behaviour, effort, ethics and accountability. Can take responsibility for *coordination*, *leadership*, process *monitoring*, and team and individual *development.*	121	221 251	321	1SP 4SP BSc

	…continued	Gen.	Cor.	Spe.	Cap.
	-To do				
XXX.D1	**Skills – general:** Can execute complex cognitive and manual procedures effectively and with *precision* and use advanced tools correctly and independently. Can *see the goal of the task*, *adapt procedures* and *visualize solutions*.	111 121	211 221 231 241 251	311 321 341	1SP 4SP BSc
XXX.D2	**Problem solving - general:** Can solve complex closed and open problems in *procedural* steps with complex, incomplete and imprecise problem descriptions. Can *reduce* a complex problem to an idealized problem and evaluate the consequences thereof. Can *diagnose* a problem*, identify* the objective, *sort* between valid and invalid solution methods, and argue a *strategy* for choosing between valid methods. Can *judge* the validity, strengths, and weaknesses of solutions. Can *interpret* the impact of the solution to the problem sphere.	111 121	211 221 231 241 251	311 321 341	1SP 4SP BSc

1.2 Programme specific elements – Biomedical Engineering

The common elements of the Programme-Qualification Matrix must be complemented by a set of programme-specific qualification elements. In *Table 3*, programme-specific qualifications are listed for the B. Sc. programme in Biomedical Engineering. This programme started in 2003, enrolls 60 students annually, and offers courses in biosignals, biomedical imaging, biosystems, bioinstrumentation, biomechanics, biomaterials, biotransport, and cellular signalling. As for the common elements in *Table 2*, the depth of learning is indicated by italicized descriptors. In the common qualifications (*Table 2*), focus is on defining the level of conceptual understanding. In the programme-specific qualifications (*Table 3*), the descriptions complement with content and context. Course numbers are real, but with department prefix removed. Course level is not indicated by the first digit, only by its placement in the four rightmost columns.

Table 3. Programme-Qualification Matrix. Biomedical Engineering

		Object complexity→

BME.K1	**Knowledge of health science:** Can *classify* cellular structures, anatomy and physiology of organ systems, and *explain* form and function with correct use of terminology. Can *analyse* and *interpret* histochemical preparations, *apply* biophysical principles, and *analyse* and *interpret* results of experiments. Can *define* diseases and *explain* pathogenesis and aetiology. Can *account* for symptoms and methods for diagnosis and treatment.	K02	K03 K11		1SP 4SP BSc
BME.K2	**Knowledge of health-care praxis:** Can *describe* and *explain* the rationale for technology applied in diagnosis and treatment. Can *explain* and *analyse* how technical factors influence the quality of clinical examinations. Can *describe* methods for evaluating accuracy and reproducibility of clinical procedures.			K04 K06	HO BSc

	…continued	Gen.	Cor.	Spe.	Cap.
BME.K3	**Knowledge of biomedical engineering:** Can *classify*, *explain,* and *interpret* facts, terminology, principles, theories, models, methods, and procedures within electrical circuits, biomedical instrumentation, signal processing, biomedical imaging, material science, biomechanics, biofluids, biotransport, and biosystems modelling. Can *apply* this knowledge to *analyse* and *solve* biomedical engineering problems.	501 502	K10 512 520 540 605 650	K05 511 522	1SP 4SP BSc
BME.K4	**Knowledge of biomedical engineering praxis:** Can *list* the major biomedical engineering companies, *describe* their product lines and *list* the main qualifications required in these companies. Can for specific disciplines *account* for praxis and regulatory induced limitations to the applications of theories, methods, and materials.	502	512 520 540 650		BSc
	-To do				
BME.D1	**Clinical skills:** Can *apply* general codes of hygiene and conduct in health-care environments. Can *assist* clinical staff in measurements, data analysis, and trouble shooting. Can *instruct* clinical staff about correct use of biomedical equipment, and their strengths and limitations.			K04 K06	4SP BSc
BME.D2	**Technical skills:** Can *setup* and *operate* systems for test and measurement and acquire data in a reproducible manner. Can *design* and *implement* software for analysis and visualisation of data. Can *perform* systems check and calibration, and make corrections and simple repair to medical equipment.	501 502	K10 540	598	HO BSc
BME.D3	**Problem solving – Investigative:** Can assist in hypothesis-driven research within cell biology and organ physiology, within signal and image processing with implementation of problem specific software, within biomechanics, biofluid mechanics and biotransport with model development, mathematical analysis, computer simulations, experiments, and data analysis.	501 502	K10 520 605	K05 522 561	4SP HO BSc
BME.D4	**Problem solving – Creative:** Can assist in need-driven development of programmable products by design and construction of analog electronics and with software development for systems control and data analysis, and of mechanical products with computer-aided design, finite element analysis, and selection of materials.	501 502	512 540 650	511 561 598	HO BSc

1.3 Programme specific elements – Quantitative Biology and Disease Modelling

The B. Sc. in Quantitative Biology and Disease Modelling is a new education started in 2016 where computational and mathematical engineering skills are taught in parallel with biology, pathology, and pharmacology. The goal of the education is for the students to be able to develop quantitative mathematical models of biological and pathological processes. The programme-specific qualifications for the B. Sc. programme in Quantitative Biology and Disease Modelling (QBDM) are listed in *Table 4*.

Table 4. Programme-Qualification matrix, QBDM

		Object complexity→			
	-To know	Gen.	Cor.	Spe.	Cap.
QBDM.K1	**Knowledge of biology, physiology and health science:** Can *classify* cellular structures, anatomy and physiology of organ systems and *explain* form and function with correct use of terminology. Can *analyse* and *interpret* histochemical preparations, *apply* biophysical and bioinformatic principles, and *analyse* and *interpret* results of biochemical experiments.	K02 002	K03 K11 022 023	088 089	1SP 4SP BSc
QBDM.K2	**Knowledge of pathology, pharmacology and mechanisms of disease:** Can *define* diseases and *explain* pathogenesis and aetiology. Can *account* for symptoms and *describe* diagnosis and treatment. Can *explain* fundamental pharmacology and bioavailability of drugs.		K03 004	087	1SP BSc
QBDM.K3	**Knowledge of quantitative biology:** Can use mathematical modelling to *analyse* and *describe* physiological processes and disease dynamics within cells, organ systems, and populations. Can use experimental and clinical data to *calculate* and *evaluate* selected parameters of pharmacodynamics and pharmacokinetics.	K02 002 050	K03 004 633 087	088 089	1SP 4SP HO BSc

QBDM.D1	**Experimental skills:** Can *design* and *perform* quantitative biochemical, molecular biological and pharmaceutical experiments and *collect* data with understanding of technical error. Can *design* and *implement* computational software for analysis and visualisation of quantitative data.	002	023 087	088 089	1SP HO BSc
QBDM.D2	**Mathematical modelling skills:** Can *perform* mathematical modelling of physiological and pathophysiological systems and *apply* this to *analyse* and *predict* the quantitative effect on changes in biological input. Can *perform* simple PK/PD modelling of drug bioavailability.	002 632	004 050 087 601	088 089	1SP BSc
QBDM.D3	**Problem solving – Investigative:** Can assist in hypothesis-driven research within cell biology, organ physiology, and disease mechanisms with identification of contributing biological factors model development, mathematical analysis, computer simulations, experiments, and data analysis.	K02 002 050 402	004 023 K11 087	088 089 015	4SP BSc
QBDM.D4	**Problem solving – Creative:** Can assist in need-driven development of mathematical models for identification of knowledge gaps, new molecular disease targets, and bioprocessing of pharmaceutics.	002 050	004 K11	088 089 015	4SP BSc

1.4 Programme specific elements – General Engineering

The General Engineering programme is a new international education started in 2016 with approximately half of the students and lecturers having an international background. The education focuses on general engineering competencies and combining these in a cross-disciplinary manner. Further, the programme has great emphasis on Design-Build already from first semester. The students are introduced to the programme's four focus areas—Living Systems, Cyber Systems, Cyber Materials, and Future Energy—and in the following semesters, they will specialize in one of these areas. The four cross-disciplinary specializations makes the programme specific elements very diverse. However, the qualification elements can still be organized according to the principles suggested in Table 1.

Table 5. Programme-Qualification matrix, General Engineering

		Object complexity→			
	-To know	Gen.	Cor.	Spe.	Cap.
GE.K1	**Knowledge of living systems:** Can *describe* basic principles in biochemistry, molecular and cell biology, and ecology. Can *account* for cell and microbiology and organisms and *explain* fermentation technology, microbial communities or species interactions.	008 030 701	000 022 023 026 105 201 400	025 034	1SP 4SP BSc
GE.K2	**Knowledge of cyber systems:** Can *examine, select,* and *apply* algorithms and data structures in a general engineering context.	016 135 240	203 157	105 270	1SP 2SP BSc
GE.K3	**Knowledge of cyber materials:** Can *explain* the fundamental concepts of materials science and manufacturing technology. Can *apply* and *explain* fundamental materials modelling and materials visualization.	018 030 240 680	203 580	502	2SP 3SP BSc

Can *setup* and *operate* complementary characterization methods for materials properties and internal structure. Can *design, perform,* and *implement* methods for analysis of large amounts and diverse types of data. Can *apply* the fundamental organization of a computer system in a cyber-physical context. Can *design, perform,* and *implement* characterization methods for energy conversion.	016 135 402 680	023 157 203 240 685	027 141 160 205 270	1SP 2SP 3SP 4SP BSc
GE.D2	**Mathematical modelling skills:** Can *implement* and *apply* machine learning algorithms to classify and retrieve patterns in data. Can *apply* techniques from discrete mathematics in computer science and engineering.	135 601	019	105 141 160	1SP 2SP 3SP 4SP BSc
GE.D3	**Problem solving – Investigative:** Can *assist* in hypothesis-driven research within computer-based tools to manage, analyze, and evaluate biological or chemical data. Can *analyze* and *validate* computer science models based on discrete mathematics, automatons, and semantics. Can *assist* in hypothesis-driven research within methods and models for engineering materials' performance. Can *examine* the properties of a component for a range of renewable and sustainable energy technologies. Can *analyze* simple engineering problems in relation to various renewable and sustainable energy resources and technologies. Can discuss fundamental challenges of implementing sustainable energy solutions into today's society and future approaches. Can compare efficiency of current and future energy technologies.	006 016 135 202 240 402 601 631 680	019 023 157 203 260 501	027 141 160 205 270 526 611	1SP 2SP 3SP 4SP BSc

	… continued	Gen.	Cor.	Spe.	Cap.
GE.D4	**Problem solving – Creative:** Can demonstrate a fundamental understanding of living systems to *solve* engineering problems. Can *assist* in need-driven development of living systems in the context of the environment and its resources and engineered systems. Can *assist* in need-driven development of appropriate programming paradigm concept to solve a specific engineering problem. Can *design* and *construct* small and medium sized programmes. Can *assist* in need-driven development within prediction of materials properties and performance. Can select materials and *engineer* them for technical applications. Can *assist* in need-driven development within materials modelling in relation to material science and engineering. Can *select* a design of a sustainable energy system to *solve* a simple engineering problem.	016 022 135 240	023 026 105 157 201 203 260 400 684	000 008 034 141 160 205 270 526	1SP 2SP 3SP 4SP BSc

2 SUMMARY

Inspired by UNESCO's Four pillars of learning [2], the elements of the National Qualification Framework used at DTU were reorganized in a companion paper [1] into four main categories of qualifications: *-to know*, *-to be*, *-to interact*, *-to do*. In the present paper, the revised framework is used to define the educational outcomes in three B. Sc. in Engineering programmes. A set of educational outcomes common to all engineering programmes at DTU is presented, focusing on common knowledge and in particular on competencies characteristic for all engineering programmes (e.g. personal and professional mind-set, self-instruction, communication and teamwork). The common Programme-Qualification Matrix is complemented by programme-specific qualification matrices, where programme content is integrated into the outcome statements. Examples are given here for B. Sc. programmes in Biomedical Engineering, in Quantitative Biology and Disease Modelling, and in General Engineering. The proposed framework aim to facilitate both university-wide uniformity as well as programme-specific focus points. The three qualification matrices presented here, introduce four new elements of educational outcomes (knowledge dimensions, mind-set development, operative skills, and problem solving complexity) none of which previously have been considered in educational programmes at DTU, and which may be implemented while revising the programmes.

ABSTRACT

The Faculty of Engineering Science at KU Leuven is responsible for 29 Master’s programmes (incl. 5 Advanced Master’s), educating over 5000 students. In this context, quality assurance faces many challenges, not only because of its numerous programmes, but also due to varying student characteristics and student numbers per programme. In the paper presented, the quality assurance of the Master’s thesis will be highlighted.

A Master’s thesis is an essential part of an academically oriented programme, since it integrates knowledge and skills connected to a certain discipline. It is a research project in which students show whether they have acquired the appropriate academic competences to contribute independently to scientific research.

The core of the Master’s thesis quality assurance is the “Faculty committee of Master’s theses” who formulates its policy regarding organisation and quality assurance of the thesis. Over the last years, efforts have been made, especially in terms of learning outcomes, of a learning pathway regarding reporting skills, evaluation and mentoring students. The latter resulted in an elaborated educational support programme for supervising teaching assistants (TAs).

This paper will give an overview on how the Faculty’s policy was formulated and subsequent actions that have been taken regarding quality assurance of the Master’s thesis, without compromising every Master’s programme own habits and traditions. Specific attention will be given to the educational support programme for supervising TAs. Finally, future plans will be discussed.

Conference Key Areas: Engineering Skills, Quality assurance, Curriculum development

Keywords: Master's thesis, Quality Assurance, Coaching TAs, Reporting skills

INTRODUCTION

At the Faculty of Engineering Science the Master’s thesis is an essential part of the Master programmes. Each Master’s student has to complete a Master’s thesis of 24 credits during the final master’s stage. Since one academic year typically corresponds to 60 credits, a Master’s thesis forms a major part of the programme. Since a Master’s thesis has a considerable research component, most Master’s theses are therefore conducted in the research labs of the Faculty. Besides, a fair number of Master’s thesis are performed in collaboration with industry, or a Master’s thesis can also be carried out abroad as part of an Erasmus+ exchange. A major concern of the Faculty is to assure the quality of these Master’s theses, taking into account varying student characteristics and student numbers as well as each programme own habits and traditions.

1 FACULTY COMMITTEE RESPONSIBLE FOR THE MASTER’S THESIS

The core of the Master’s thesis quality assurance is the Faculty committee responsible for the Master’s thesis (FCMT) who formulates its policy regarding organisation and quality assurance of the thesis. This committee reports to the Faculty Educational Committee (FEC) that consist of all programme directors and is headed by the vice-dean Education. The committee itself is composed out of representatives of each programme, the TA’s and the students. It is chaired by the vice-dean Education, and the secretariat is taken care of by the educational development unit of the Faculty.

The committee started out as a rather administrative and practical consultative but as quality assurance became more prominent on the Faculty’s agenda, it’s mandate became more policy-focused. Over the last years, efforts have been made, in terms of refining admission procedures, formulating learning outcomes, developing a learning pathway regarding reporting skills, evaluation and mentoring students. The latter resulted in an elaborated educational support programme for supervising teaching assistants.

1.1 Admission procedures

Each Master’s programme has its own procedure to assign Master’s thesis topics to students. However, to ensure uniformity, some elements are shared by all Master’s programmes organised by the Faculty. During the spring semester of the first Master’s stage, a list of possible topics for Master’s theses is announced to the students through an online platform. In most programmes students can propose their own topic, if they find a professor who is associated with the programme and willing to act as advisor. Students are encouraged to contact researchers and professors to make an informed choice about the thesis topic they would like to pursue. For example, in some programmes this can be done during a theses fair, where coaches and supervisors are present. The topics are assigned to the students before the end of June, taking into account the preferences of the students and a fair distribution of the theses over the Faculty staff.

1.2 Learning outcomes

At the Faculty, every course is described in an ECTS course description. This file is available on the programme website. It contains a full course description, including the goals and learning outcomes of the course, the content, teaching and evaluation methods. Concerning quality assurance, well defined learning outcomes are crucial. Therefore, the committee refined the learning outcomes of the Master's thesis, in close cooperation with all stakeholders: professors, teaching assistants, students and industrial partners. This exercise resulted in learning outcomes acceptable and recognisable for all programmes:

After completion of the Master's thesis, the student:

- has set up an original research (original in the sense that the student has generated (partly) new knowledge);
- has state-of-the-art knowledge regarding the topic of his research;
- formulates the research question clearly and correctly;
- follows the developments in the field independently and can assess their relevance for answering the research question(s);
- designs a research plan, using the most appropriate and achievable techniques (based on the information found in the scientific literature) and executes it;
- analyses and interprets the obtained results;
- has a critical attitude towards (own) research results;
- considers optimization (context and (suboptimal) prerequisites) and always keeps track of uncertainties to define boundary conditions;
- can report about his research in a coherent way, where adequate attention is given to: correctness of the displayed information (state-of-the-art), understandable and clear within the discipline, scientific language, correct Dutch or English, the layout of the text, references, tables and figures that meet the specified formal requirements, etc.;
- has an academic correct attitude in relation to references;
- creates a decision-making process where the obtained results are framed in relation to the state-of-the-art (also demonstrating what the student has imparted to the state-of-the-art);
- can report orally about his research, in which due consideration is given to: situating the research within the discipline, presenting in an attractive way, the structure and coherence of the presentation, the scientific language, respecting the time constraints;
- can answer in scientifically correct language to questions from both fellow students and researchers from the discipline;
- has demonstrated a critical self-reflective attitude, an active commitment, a large autonomy and to be able to work in a team (if applicable).

1.3 Supervision and mentoring

During their Master's thesis, students are provided with qualitative guidance. All Master's students have a Master's thesis advisor, usually a professor associated with their Master's programme. Besides, students are guided by a teaching assistant, who is more closely connected to the Master's thesis and acts as a mentor for the student.

There is regular contact between the student and his mentor, usually (but not always) on a weekly or biweekly basis. The mentor tracks the progress of the student and acts as a first access point for advice and other resources. However, all initiatives on reports and progress meetings must come from the student. Besides regular meetings with the mentor, students meet their advisor at least once or twice per semester. Thus, the mentor has a close understanding of the Master's thesis progress and informs the advisor regularly.
In some cases the coaching can also be performed by the advisor himself. When the Master's thesis is done in close collaboration with a company or other organisation, the student will be coached both by an employee of the company, as well as by a faculty member of Engineering Science. During the academic year, the students are asked to formally report on the progress of the Master's thesis. Depending on the programme this can be done once or twice during the year. Furthermore, depending on the programme, the students are asked to keep track of the work they have done, e.g. through a time sheet or a blog.

As the teaching assistants play an important role in the guidance of the Master's thesis student, the Faculty provides qualitative educational training sessions, described in detail in paragraph 2. Furthermore a memorandum describing the Faculty's vision of qualitative mentoring was written. Specific attention was given to the different roles and responsibilities of mentors as well as promotors.

1.4 Reporting skills

The main deliverable of the Master's thesis is the Master's thesis text, which can include appendices with descriptions of code or experimental data. In some programmes, also a paper is required, or a paper/poster in a style appropriate for a non-specialist audience. The Master's thesis can be submitted at three moments of the academic year: June 6th, August 21st, and January 15th. In some programmes intermediate deliverables, such as a literature review, are required.

To enhance the quality of these reports, The Educational Development Unit of the Faculty, in co-operation with the University Library, organises Master's Thesis workshops about information literacy, intellectual integrity and plagiarism and academic writing. These workshops aim to support the writing process of the Master's thesis:

- Workshop to recapitulate on literature search in the library and its extensive e-collections (Information Literacy);
- Workshop to refresh the principles on academic writing (Academic Writing);
- Workshop on integrity

1.5 Evaluation

The evaluation of the Master's thesis applies both to the process and the product and is done by a commission that consists of the advisor, the mentor and two additional assessors with sufficient expertise.
Each student has to give a final presentation of at least 15 minutes, and answer to the questions of the jury during an oral defence.
To ensure the quality and consistency of the evaluation of the Master's theses, the Faculty developed an evaluation sheet (table 1) and an assessment Scale (table 2). Table 2 is not a grading matrix, but contains criteria that have to help the assessors situate the master's thesis within the different aspects. The final obtained mark is a

weighted average of these different aspects. The evaluation sheet of table 1 needs to help jury members weigh the various aspects of the thesis in order to reach a final score.

Table 2. Evaluation sheet

	Insufficient	Poor	OK	Good	Very good	Excellent
Global evaluation						
1 Research aspect						
1.1 Content, i.e. *Research question* *Review of literature* *Approach and methodology* *Interpretation of the results obtained* *Conclusions*						
1.2 Final report i.e. *Accuracy* *Intelligibility* *Depth* *Style* *Language* *Lay-out* *Tables and figures* *References*						
1.3 Presentation i.e. *State of the art* *Presentation* *Explanation* *Language* *Time management* And the defence i.e. *Answers to the questions* *Defensibility* *Clarification*						
2 Additional assignment						
3 Method i.e. *Dedication* *Planning* *Autonomy* *Half-term report* *Teamwork*						

Table 1: Assessment scale

Score	Research quality, personal contribution and originality	Insight into the subject matter	Methodology	Quality of text and presentation	Histogr.*
19- 20	Master's thesis of high research quality that exceeds expectations. The personal contribution is high **and** the work is characterized by a high level of originality from the student.	The student has insight and can discus with experts within the domain.	A correct methodology was used, characteristic of the discipline.	Text and presentation of excellent quality.	0.9%
18-18.9					3.9%
17-17.9	Master's thesis of good research quality. The personal contribution is high **and/or** the work is characterized by a high level of originality from the student.	The student has insight and can carry on a meaningful discussion with the members of the jury.	A correct methodology was used, characteristic of the discipline.	Text and presentation of very good quality.	11.1%
16-16.9					12.3%
15-15.9	The quality of the master's thesis meets the expectations. The personal contribution and/or the work is characterized by a good degree of originality from the student.	The student has insight and can have a discussion, albeit limited.	A correct methodology was used, characteristic of the discipline.	Text and presentation of good quality.	19.2%
14-14.9					17.2%
13-13.9	The quality of the master's thesis meets the expectations. The degree of personal contribution is limited and the work is characterized by a rather limited degree of originality from the student.	The student has mastered the topic, but has no insight into the wider domain.	A correct methodology was used, characteristic of the discipline.	Text and/or presentation of moderate quality.	12.9%
12-12.9					8.4%
11-11.9	The quality of the master's thesis only just meets the expectations. No personal contribution has been made and the work is characterized by a very low degree of originality from the student.	The student has mastered the topic, but has no insight into the wider domain.	Small methodological mistakes that do not influence the conclusions of the work.	Text and/or presentation are poor.	6.6%
10-10.9					5.1%
9-9.9	Poor, but remediable in the short term. The amount of work and/or the reasoning does not meet the expectations.	The student has only mastered the subject to a limited extent.	The conclusions of the work are questionable.	Text and/or presentation of insufficient quality.	0.9%
8-8.9					0.5%
<8	Poor, not remediable in the short term. The amount of work and/or the reasoning does not meet the expectations.	The student has not mastered the subject.	The conclusions of the work are questionable.	Text and/or presentation of insufficient quality.	0.9% **2012-'15*

2 EDUCATIONAL SUPPORT PROGRAMME FOR SUPERVISING TEACHING ASSISTANTS

2.1 Training?

Every academic year, about 200 new PhD students start their research at The Faculty of Engineering Science. Most of them will teach students and coach Master's theses. Therefore, the Faculty provides an educational training programme for these teaching assistants (TAs). In September 2014, the new training programme SWEET² or 'Starters Week of Engineering and Education: Training for TAs' was introduced. Besides enhancing the TAs' teaching skills, the improvement of the quality of education is aspired. The guiding principle in developing this TA training is the 'teach as you preach' principle.

SWEET² consists of a number of thematic training modules organised during the first week of each semester. Every training module consists of two 2-hour sessions and two corresponding preparatory assignments. These sessions focus on dealing with frequently occurring problems, activating students, providing feedback, and the implementation of modern technology in the teaching practice. The first session strives for providing TAs advice before they start their teaching assignment. During the second session, the emphasis is reflection on their teaching experience and feedback. In order to enable more interaction between the TAs and to facilitate peer learning during the TA training, we introduced blended learning by asking the TAs to make a preparatory assignment before each session.

According to the 'teach as you preach' principle, each module departs from one specific teaching format that corresponds to the teaching practice of the TAs, such as supervising exercise sessions or coaching Problem-based Learning. During the sessions the SWEET²-coaches utilise teaching methods that are considered desirable to be put into practice by the TAs during their own teaching assignment.

2.2 Specific training module 'Guiding a Master's thesis'

Within the training module Guiding a Master's thesis, the importance of clear agreements is highlighted and the TAs receive tips and tricks on guiding a student. In accordance with the 'teach as you preach' principle, the teaching formats refer to the one-to-one relationship of the TA with the student. During a roleplay for example, cases are given and the participants should react as a TA or a student. Besides, the structure of the module corresponds to the different steps in the Master's thesis process throughout the academic year, like defining the subject, getting started and giving feedback.

2.3 Evaluation of the module 'Guiding a Master's thesis'

The module 'Guiding a Master's thesis' was implemented in its current format in September 2015. To ensure the quality of the sessions and to further optimize them, the instructors asked the participants to write down three positive aspects and three points that need improvement, after each session organised during the SWEET²-weeks of September 2015, February 2016 and September 2016.

Overall, the feedback of the participants was positive, as shown in tables 3. 74% of the participants gave 3 positive remarks, whereas almost 51% gave less than 2 negative remarks. The interactive format was thoroughly appreciated (62%) out of 193 participants. The 'teach as you preach' principle, was recognised and mentioned explicitly as positive by 5% of the respondents. The materials used during the sessions turned out to be helpful, as 34% of the respondents mentioned them. In particular a testimonial video where professors explain their view on guiding Master's theses was inspiring for 19% of the respondents. 6% of the respondents would even like to see more of these videos. The concept of student archetypes,

developed to help identify different types of students and how to adapt your communication style accordingly was appreciated by 20% of the respondents. Another positive aspect was the use of hands-on guidelines and tips (18%). However 18% of the respondents would wish to discuss more examples of real-life cases.
In September 2015 13% of the respondents acknowledged that the relevance of some of the exercises was not always clear to them. In order to improve this, efforts were be made to make the relevance of the exercises and the cohesion of the session more clear to the participants. This resulted in a more positive evaluation of that aspect in February and September 2016, respectively 23% and 22% of the participants mentioned the cohesion and relevance of the exercises as a positive aspect.

Table 3: Number of remarks 'Guiding a Master's thesis'

	3 remarks	2 remarks	1 remark	0 remarks
Sessions *(# 193)*				
Positive	74,09%	23,32%	2,59%	0,00%
Negative	23,83%	25,39%	41,97%	8,81%

3 DISCUSSION AND CONCLUSIONS

All efforts in terms of refining admission procedures, formulating learning outcomes, developing a learning pathway regarding reporting skills, evaluation and mentoring students resulted in a supported and coherent framework. This framework allows the faculty to continuously monitor and develop the quality of the master's theses without compromising each programme own habits and traditions.

Maintaining and continuing this framework is one of the challenges for the Faculty in the future. In this perspective, the FCMT is the key actor in coordinating all the different aspects and stakeholders involved. It is important to allow the committee to establish an efficient quality developing process while keeping a balance between bottom-up and top-down concerns. In the future, a relapse to the original more administrative and practical mandate can be considered as a thread and should be avoided. Therefore, close attention will be paid to keep the FMCT's mandate content-focused.

In this paper specific attention was given to the development and evaluation of the educational support programme for TAs mentoring theses. The implementation was successful and the participants evaluated the training module positively. As discussed above, the possibility to interact during the sessions was highly appreciated by the TAs: working in group, sharing experiences and discussing problems that occur during their teaching assignment were mentioned as positive aspects. Furthermore, the respondents gave positive comments about the content, teaching formats and materials used during the sessions.
Efforts were made to make the rationale and cohesion of the session explicit, which was successfully proven by the subsequent evaluations. In the nearby future, more elaborated use of real-life cases is a suggestion that will be taken into account by SWEET^2-coaches to further improve the module.

ABSTRACT

Over the past two decades there has been much discussion about how to best educate Engineering Managers. Indeed, traditional Management Education within Business School Settings has been subjected to considerable criticism, with, some suggesting that traditional MBA programmes lack engineering context and application and thus fail to meet the needs of both employers and students. Conversely, others postulate that Business Schools provide graduate students with <u>generic</u> skills and <u>transferable</u> competencies and are thus exactly engineering managers *should* be educated. Looking critically at Engineering Management Education within an Engineering School, this paper suggests that graduate level Engineering Management Education needs to be led by Engineers who have experience in industry and who also are qualified in management. It introduces a model of organisational change developed specifically for an Engineering Education setting and considers how that model may be best applied to an Engineering Management Education setting.

Key words: RVS, Graduate Students, Engineering Management Education

1) INTRODUCTION

Set within a global workplace where professional engineers need to be multi-skilled practitioners able to work in multi-disciplinary teams , the matter of how to best educate those individuals who find themselves with managerial responsibility for major engineering projects is of great importance. Yet the question of how and where management training should be included within an engineer's career path is rarely discussed; with many professional engineers looking outside their employers' vocational offerings and beyond traditional university engineering education to access management training from graduate level Business Schools. Such business-centric education has been subjected to considerable criticism, with some suggesting that traditional MBA programmes lack engineering context and application and thus fail to meet the needs of both employers and students [1]. On the other hand some literature suggests that Business Schools provide graduate students with generic management skills and transferable competencies and are therefore exactly what engineering managers *should* be accessing as an opportunity to broaden their thinking [2]. In looking at both sides of the argument, what is clear is that engineers who take on management responsibilities should be trained; and because most engineers do, at some time in their career, find themselves working at a management level, this training needs to be appropriate to an engineering context. Despite this, the question of how and when management training should be accessed by engineers, or what it should comprise in terms of practice, focus and theory, remains largely unanswered.

In seeking to explore this issue, this paper looks at engineering students' experiences and perceptions of a management module that is embedded into graduate level engineering education. The module, which provides students with key Project Management knowledge, theory and skills, has been carefully constructed around an approach to engineering education developed by the paper authors [3]. Termed the RVS Model of Engineering Education, the approach comprises three key concepts, Relationships, Variety and Synergy and is built around the concept of 'Synergetic Configuration'. The study upon which this paper is based critically discusses students' perceptions of the Project Management module that has been synergistically configured so as to encapsulate key engineering, managerial and educational requirements. The paper builds on previous studies to show how the RVS approach to engineering education can be a catalyst for educational change. In this case it is in teaching engineers about management, thus adding to key discussions in the area of management education for engineers.

2) BACKGROUND

In a pre-Brexit UK Government Report, Member of Parliament Vince Cable, who was at the time Secretary of State for Business, Innovation and Skills commented "*A strong British engineering sector is vital to the long term sustainability of our economic recovery, and increasing the supply of engineers is at the heart of this*" [4]. Indeed, both before and after Brexit, the importance of engineering to a thriving UK economy is frequently featured in the British press with arguments that 'engineering skills shortages' comprise a present and future threat to the success and security of the country being a favoured topic [5,6]. From a more global perspective, it is evident that much of the world acknowledges the important role that Professional Engineers play in both solving transnational problems and challenges including issues around: Sustainability and Sustainable Development: Political unrest, terrorism and war: Global warming and pollution: An aging infrastructure, and, as we move into the 21st Century: International cyber security and artificial intelligence [7].

Set against this challenging environment, the need for those managing engineering projects to be able to understand science and maths and to be in a position to solve engineering problems, whilst adopting sound managerial practices, has become increasingly important, with much debate focusing on the need to promote leadership and management skills within the engineering workforce [8,9]. Yet in many areas, engineering projects are managed by non-engineers who, whilst being 'professional managers' have little or no understanding of the underpinning engineering or scientific theories. At best this can result in financial and project mismanagement, whilst at its worst technical errors could result in loss of life and a damage to the environment. Hence the need to educate engineers with managerial skills is increasingly important. In seeking to address this, business and management modules have been introduced into many graduate level engineering programmes. The P^3 Project looked at one such module. It examines the issues around applying the RVS approach to management training for engineers so as to 'Synergistically Configure' the curriculum and in doing so promote pedagogy and practice within graduate engineering education.

- **Introducing Synergetic Configuration: An Approach to Engineering Education developed by Engineering Educators *for* Engineering Education.**

Synergetic Configuration is defined as "*the requirement that university level Engineering Education should equip students with the technical capabilities required by industry, whilst providing them with a sound theoretical knowledge base, within a supportive curriculum in which 'softer skills' are embedded alongside technical competencies and independent learning is the norm*". Grounded in the findings of previous studies and published work by the paper authors, Synergetic Configuration has emerged out of a new model of Engineering Education developed by the paper authors, the RVS Approach to Engineering Education [3]. Synergistically synthesizing three distinctive concepts, Relationships, Variety and Synergy, and developed with the intention of promoting Scholarship in Engineering Education, the model has been specifically developed so as to overcome the linguistic and conceptual barriers many engineering educators encounter when trying to engage with pedagogic theory. As such it has helped to facilitate change in an environment that typically struggles to adopt new ideas quickly and holistically [10].

In considering how to promote Scholarship in Engineering Education the paper authors turned to the work of Boyer [11] who argued that there are four separate, but overlapping, areas of Scholarship (Discovery, Integration, Application and Teaching). Each of these four areas was considered in the development of the RVS Approach from an Engineering Education perspective. Synthesized with the three different concepts that make up the RVS approach, the foundational use of Scholarship as an educational ideology resulted in a theoretically grounded and academically relevant pedagogy specifically aimed at those working in Engineering Education.

From an Engineering Education perspective, the first area of Scholarship, that of Discovery, is encapsulated by the pursuance of knowledge which underpins engineering pedagogy and research. Following on from this the Scholarship of Integration is evident within an Engineering Education context when considering the inter-connectivity across different engineering disciplines, particularly when taking account of the vital role engineers play in society. Within the RVS approach the Scholarship of Integration encourages learners and teachers to seek answers beyond traditional disciplinary boundaries in a manner that is *imaginative*, *interdisciplinary, interpretive* (and) *integrative* (Boyer, p 21). The third area of Scholarship, Application, represents the fundamental basis of much engineering education, indicative of the fact that engineering is an applied discipline and as such requires the acquisition *and* application of knowledge, competencies, skills and contextual insight. The final area of Scholarship, Teaching, represents the fundamental purpose of the model, which is to provide an easily adaptable, scholarly approach to engineering education. In bringing together three distinctive concepts of Relationships, Variety and Synergy the paper authors have produced a useful and useable model which has been tested over a number of years. The P^3 Project aimed to take this testing one stage further and set out to critique how proactive synergetic configuration of pedagogy, practice and procedure within different elements of a graduate level engineering management programme can act to promote a positive learning experience at graduate level.

3) THE P ^{3} PROJECT METHODOLOGY

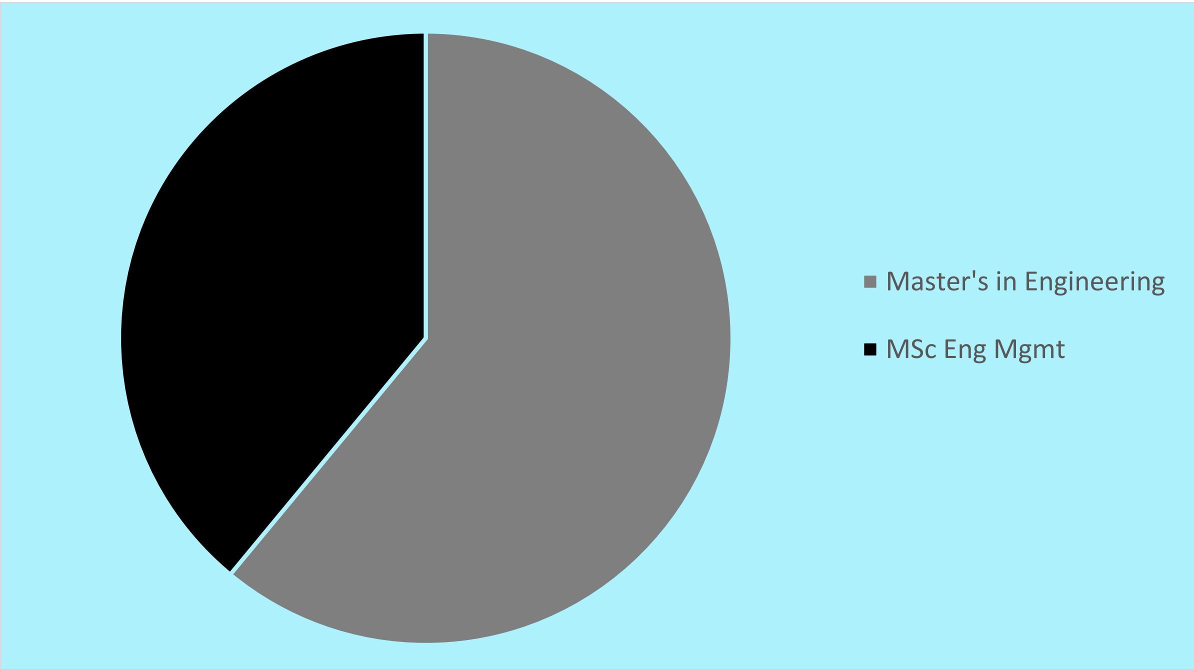
To achieve this aim, an Action Research Approach [12] was adopted in which the project leaders set out to answer the question *"How can pedagogy, practice and procedure be improved through the application of the RVS model of engineering education at graduate level?"* A small exploratory study was conducted focusing on pedagogy and practice within an Engineering School based in the UK. A survey tool was developed and administered to a cohort of 80 engineering students studying Engineering Project Management. The response rate was 75% (61 students). The survey itself was divided into three main themes, each one relating to the key concepts of the RVS approach to engineering education: Relationships, Variety & Synergy. Each of the concepts aligns with one of the three areas upon which the P^3 study was focused: Practice (Relationships): Pedagogy (Variety): Procedure (Synergy).

This paper uses descriptive statistics only at this stage in an attempt to gain some insight into students' background and experiences. The reasons for this is reflective both of the small sample size, and of the fact that the study aims to directly impact practice. The next stage of the work will be to conduct in-depth interviews with students studying engineering management.

- **P^3 Project Sample**

The sampling field comprised a cohort of 80 students studying either an MSc in Engineering Management or an MSc / MEng in a range of different engineering subjects, including Chemical Engineering, Design Engineering, Mechanical Engineering and Computing Science amongst others. The respondents were divided into two main groups as shown below in Figure 1. Just under two-thirds of the cohort were enrolled on a technical MSc / MEng Programme, with the rest, all graduate engineers, studying for an MSc in an Engineering Management related discipline.

Figure 1: Programme of Study: Percentage of Sample (*N* = *61*)



In looking closely at the demographic makeup of the respondents it was noted that just under a quarter of the sample were female; this is typical of the School of Engineering in which the study was conducted

Figure 2: Demographic Breakdown of Sample: Gender

Gender	*N*	%
Male	47	77
Female	14	23
Total	61	100

In considering the issues around engineers in management, one of the key variables which emerged out of the literature related to individual work experiences, particularly when considering graduate engineers. Figure 3 shows that the majority of the sample had undertaken a period of paid internship as part of their undergraduate training. This figure, which for the UK is quite high, is indicative of the School of Engineering & Applied Science in which the study occurred, whereby all undergraduates are strongly encouraged to participate in a year-long formal work experience. This is usually paid and is, where possible, at graduate level.

Figure 3: Sample work experience

Work Experience	%
Undergraduate internship	54
Part-time work whilst studying	9
Engineering management role	8
Engineer	5
Consultant Engineer	2
Other	7
None	15
Total	**100**

4) THE STUDY FINDINGS

This section focuses on the study findings. It is divided into three sections, each one looking at a different area explored in the P^3 Study.

- **Exploring relational issues in engineering management education**

The first part of the study focused upon the importance of developing a practice-based approach to teaching that encourages positive work-study relationships amongst the cohorts. The importance of relationships in education is discussed elsewhere [3] and is viewed as particularly important for engineers who, upon graduating, may soon find themselves responsible for managing teams of people from a wide-range of backgrounds and disciplines with different levels of knowledge and understanding.
The Project Management module was carefully constructed so as to encapsulate the main theoretical and practical issues around Project Management. Human relations is key to this, and thus the assessment requires high levels of cross-cohort collaboration and communication. The student-focused approach adopted by the module lecturer represents an important part of learning as the students are encouraged to view the lecturer’s interactions with them as a role model in terms of how to manage disparate groups and situations. In total, seven relational-practice focused question-statements were asked. Whilst a five point Likert scale was used in all of the questions, the

differentiation between the levels of agreement and disagreement was not valid; hence the 'agree and strongly agree' data (denoted as A) and 'disagree and strongly disagree' data (denoted as DA) are merged together. This provides a clearer picture of the students' perspectives. The numbers of those students who either agreed or disagreed with the statements is given below.

Figure 4: Relational (Practice focused) Questions

In thinking about the Project Management module the following applies…	**A**	**DA**
The group work in this module has enabled me to build some close friendships	**47**	**11**
The group work has provided the opportunity for me to develop my communication skills	**53**	**4**
The fieldtrip has provided the opportunity for me to get to know my classmates better	**48**	**10**
I have found the module lecturer approachable throughout	**54**	**2**
I found it difficult to work in a group	**20**	**39**
The opportunity to gain feedback in stages has helped me develop my understanding of PM	**49**	**6**
The class visit by a Project Manager helped me appreciate the real world PM context	**55**	**1**

- **The Importance of Variety in Pedagogy**

Having examined the issues around relationships in teaching and learning practice, the survey then turned to the question of variety in pedagogy. In seeking to expose students' to a range of different scenarios and situations the module leader aimed to provide an interesting and relevant learning experience. One of the key aspects of the Project Management module is the manner in which management of engineering projects has changed over time. This is contextualised by a fieldtrip to a heritage site in which students are encouraged to look at the different socio-economic, engineering and political issues associated with project management from the end of the 18th Century through to modern-day practice. The location used for the field trip is part of a UNESCO World Heritage Site. The site is Cromford Mill and it is considered to be the first factory established anywhere in the world [13]. The questions asked in this section therefore focused both on classroom activities but also included a look at students' perceptions of the value of the fieldtrip. Figure 5 presents the 7 question statements asked and the data is again disaggregated into 'Agree' (A) and 'Disagree' (DA).

Figure 5: Variety in Pedagogy Questions

In thinking about the Project Management module the following applies…	**A**	**DA**
The different learning and teaching approaches used in the module made the lectures more interesting	**57**	**0**
The different learning and teaching approaches used in the module made the content more understandable	**56**	**1**
The use of case-studies has helped me appreciate the range of practical project management issues	**55**	**2**
The class discussions have been valuable in helping me understand the main issues	**50**	**6**
The lectures provided the foundational knowledge necessary to study the subject independently	**57**	**4**
The visit to Cromford Mill was interesting in helping me understand the concept of industrial heritage.	**50**	**6**
The presentation at Cromford Mill was useful in helping me comprehend some of the practical issues associated with PM	**60**	**1**

- **The importance of Synergy in Pedagogic Practice**

The final area explored by the survey related to the manner in which the module leader had purposefully and synergistically aligned all aspects of learning and teaching. Figure 6 provides an overview of the disaggregated data relating to the 10 questions posed.

Figure 6: Synergy in Pedagogic Practice Questions

In thinking about the Project Management module the following applies…	A	DA
The module content is relevant to modern day engineering	60	1
The module content is applicable to the coursework	60	1
The group work in the module is good preparation for work	57	4
The real life case-studies helped me understand the theory	53	8
The visit to Cromford Mill helped me gain a wider perspective on PM	46	9
The visit to Cromford Mill has given me an insight into the importance of heritage within contemporary society	51	7
The visit to Cromford Mill brought PM to life	51	10
The module learning outcomes have been achieved	60	1
The assessment is appropriate for developing my PM skills	58	3
The module content is relevant for a career in industry	59	2

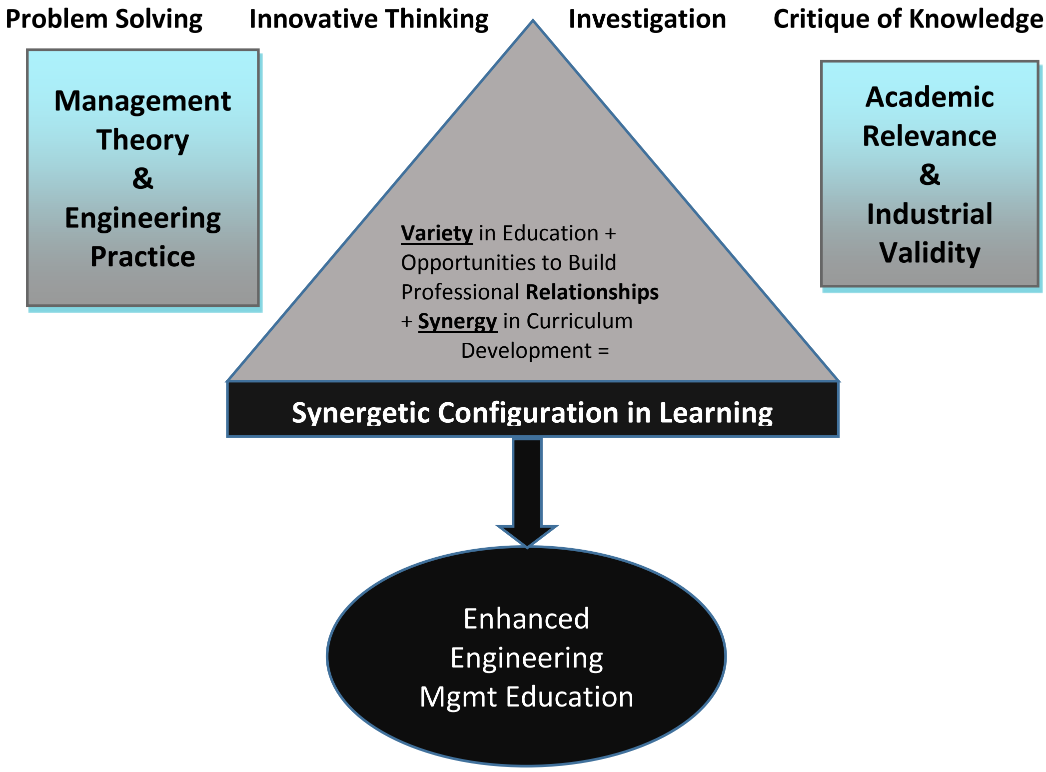
5) DISCUSSION

Based upon the emergent research findings, a conceptual framework was developed. Depicted overleaf in Figure 7, the framework highlights the centrality of the main three concepts of the RVS formula [3]. In further developing this approach, the paper authors drew upon a meta-analysis of the findings of *a priori* educational research studies they were directly responsible for leading; the largest one of which examined the experiences of around 1,000 undergraduate students and found that the most important driver of student success is a 'sense of belonging' [14,15].

An important facet of belonging, learning and professional *Relationships* represent a key part of student success. Whilst some colleagues appear to believe that students' professional relationships have little or nothing to do with engineering education, the fact is that following graduation, personal and professional networks are often key to success in engineering and management roles. Thus, in educating engineering managers, there is a clear need to identify mechanisms by which 'networking' and 'communicating' may be taught and assessed.

The second component of the RVS formula, *Variety* applies directly to innovative engineering education **and** practice. In engineering management education, the concept of *variety* requires educators to take account of students' individual learning preferences and styles, whilst factoring in their differing demographic, professional and educational backgrounds [16,17,18]. Additionally, it is also important that educators consider the future different disciplinary settings that the students, once they are employed as engineering managers, will be working in.

Figure 7: Emergent Conceptual Framework: Synergetic Configuration in Engineering Management Education



The final component of the RVS formula, *Synergy* needs to be applied at all levels of learning. In an engineering management module this means purposefully constructing learning experiences that synthesize and synergize engineering contexts and problems with real-life management tools and approaches. In applying a formulaic approach, the application of the RVS approach results in Synergetic Configuration and leads to enhanced student experiences, retention and success. The link between the quality of learning and teaching and student success is reflected in the literature [19,20], with much of the contemporary academic debate built upon the concept of Scholarship proposed by Boyer [11,21]. In educating engineering managers the application of the RVS approach to pedagogic practice means that each distinctive strand of scholarship is considered to be central to student success.

6) CONCLUSIONS

As engineering teachers, we are confronted with the challenge of engaging a diverse student body in a discipline that is multi-faceted with the aim of preparing them for future employment. Often, when speaking to alumni, the role they fulfil after graduation is more reliant on the life skills they have developed during their university education rather than the technical content of the programmes they have been studying. This is reflected in the literature and often discussed as skills development [22].

Courses such as the one described here, expose students to authentic settings with real problems and issues that need addressing. Whilst engaging with the learning context as an interested and knowledgeable observer, students quickly begin to appreciate the multiplicity of opportunities a career in engineering can offer.

In conclusion, too often, the need for accreditation, study of discipline content and traditional pedagogy frame the learning environment. Certainly innovation in learning and teaching through active approaches and industry engagement are welcome, but perhaps now is the time to move the debate forward and start to consider our students as taking an 'engineering role' rather than being an 'engineer' on graduation [23]. Clearly more work needs to be done in analysing this data and exploring the subject further, but now is certainly the time to challenge the status quo.

ABSTRACT

The role of quality agencies changes because quality of institutions increases thanks to the regular intervention of those agencies since a couple of years. We can observe that periodic evaluation has really upgraded quality of HEIs; but this quality increase can also be attributed to interventions of international organizations such as ENQA (European Network for Quality Assurance) or ENAEE (European Network for Accreditation of Engineering Education with EUR-Ace label) that work on the standards of quality assurance at the European level.

So new criteria arise, suggested by stakeholders or by members when members come from a socio-economic college for example. It is a new concept because in some cases we are far from considerations concerning the teaching of science and technology.

In this paper we will see how this phenomenon take place as well in generalist agencies as in an engineering education dedicated agency but very often, much more in those; the learning outcomes approach has also a strong role in this evolution.

Then we will present the devices that CTI (Commission des Titres d'Ingénieur: French Accreditation Agency for Engineering Education) has put in place in this frame in three specific domains: innovation, sustainable development and health and safety at work.

Conference Key Areas: Quality Assurance and Accreditation, Sustainability and Engineering Education, Ethics and Engineering Education

Keywords: accreditation agency, sustainable development, innovation, health and safety at work

INTRODUCTION

Even in the academic world, the definition of engineering is changing; in the last Global Engineering Dean Council forum, engineering was defined as a mean to increase the quality of life of people: it is not surprising that accreditation changes too.

Previously, experts of accreditation agencies were much more seen as « Constables » coming in the institutions to verify if everything was right, now they are very often considered either as prescriptions makers or counsellors on specific points, this shows that in the minds of the deans as well as in those of the members of those agencies things are changing. But this is not evident for all the deans because a few of them are always thinking that accreditation agencies should stay on fundamentals such as mathematics or physics and not go through all these “peripheral” matters.

The “Commission des Titres d’Ingénieur” is particularly concerned by this evolution because it includes both academic and socioeconomic members and those are directly concerned by economy and so by society. As we exist since 1934, and have defined periodic institution since 1997 (which is a rather long period of time) some questions are arising about simplification and evolution of the process and criteria of our audits; but the evolution of these criteria also appears as driven by quality considerations including ENQA’s and ENAEE’s (since 2007 when we decided to become member of ENQA and to conform our processes to its requirements).

These criteria linked to society can be of very different kinds according to the continents and even the countries, in this paper we will focus only on some of them.

1 THE FACTORS LINKED WITH THE KIND OF AGENCY

Depending on the country, engineering is evaluated by generalist agencies or engineering devoted, or both. It is interesting to compare the importance of societal criteria in both systems.

1.1 Generalist agencies

The number of quality agencies increases singularly since 10 years. In our country there are 2 agencies belonging to ENQA, one of them (HCERES) is generalist and the other one (CTI) dedicated to engineering education. Some of the engineering institutions are evaluated by both agencies.

If we compare the criteria of the two agencies, we see that, for example, for the moment, criteria such as Sustainable Development (SD) are not really taken into account in the generalist agency criteria.

There are several reasons for this:

-Sustainability is in fact taken into account by a law in France: “loi de Grenelle” that make mandatory the fact that universities deal with it, so the criteria of the generalist agency do not deal with mandatory things, even if this law is not really applied!

-There are many labels concerning SD that have been developed by private associations concerning either Universities or “Grandes Ecoles” or both and the fact that the HCERES deals as well of medicine, art, or engineering makes it not easy defining the good criteria linked to society concerning all fields of education.

It is the same for other criteria for example “health and security at work”, however “innovation” which is a great consideration of French government and for which money is given to institutions to develop a device called PEPITE, is considered by HCERES. This shows however that those links between society and accreditation depend on the factors linking specifically politics of education and economy (money given for the PEPITE device for example).

HCERES considers more the research and education strategy of the institution and the opportunity of success that this strategy will have, than details: if a University thinks that sustainable development or health and security at work is a strong differentiation point of its strategy, it can describe it in its Self-Evaluation Report.

If we have a glance on ESG proposed as reference by ENQA (generalist agency), we find that “according to the European desire to constitute a society based on knowledge, higher education is a basic point of the socio economic and cultural development”. So, in ESG 1.9, we find the criterion:
“Institutions follow and evaluate periodically their programs so as to insure that they reach the aims they defined and that they answer to the needs of students and society. With the following guidelines:” The follow up, evaluation and periodic revision of programs aim to guarantee that the offer stays appropriate and to create an apprenticeship surrounding efficient for the students”; among the devices suggested to realize this criteria: “Taking account of the needs in constant evolution of the society”.
Those guidelines let to the institution a very large opportunity to take into account the needs of society but, as they are guidelines and not criteria, it does not really make things mandatory for institutions.

1.2 Agencies dedicated to Engineering Education

If we have a look now on the agencies dealing with engineering education, we can compare for example EUR ACE criteria and other specific agency like CTI or ABET for example.

This comparison is very interesting: it shows that factors linked to society appear in both agencies but not at the same compulsory level.

ABET has among its criteria the following one: “a knowledge of contemporary issues”, this can be applied to many fields [2].

EUR-ACE has defined criteria and guidelines: criteria are mandatory, guidelines can either be considered as explanations of criteria or possible ways to answer to the criteria, they are not mandatory. In EUR-Ace we find the criteria linked to society in the guidelines. ENAEE is a European agency and the state of development of society in not the same in every country, so ENAEE cannot oblige all European countries to have the same criteria linked to society and development. We can again notice that politic factors (for example human rights considerations and policy for sustainability) also intervene in this field.

2 THE FACTORS THAT CAN ALSO PLAY A PART IN THIS KIND OF POLICY

2.1 Accreditation agencies are not always seen as acting in good directions for the future of society

The paper recently published by MIT [1] about universities of the future shows that there is a tension between what engineering science professors want to teach engineers to do, so that they can become young scientists and PhD students and the needs of the government and society, which is to create engineers to contribute to economic development and growth.

The role of quality and accreditation agencies can be either to make this tension progress or resolve it in the future decades. At the same time people think that in countries like China, India, Brazil or Canada, the accreditation agencies leave little room for new ideas and experimentations, this means that it appears that accreditation agencies should better act in favour of needs of societies if we want that things change.

It is a very important question for the agencies, what is their precise role: we can answer that it depends on their statute: are they academy driven or government driven? The good answer is in between and the necessity of independence given by ENQA could perhaps insure this good equilibrium.

However, for example, on questions linked to new pedagogies, things are not so evident because teacher's habits are strong, but money is often given by government and very often those new pedagogies are in relation with this policy (introduction of SD for example).

2.2 Basic accreditation or follow up?

Very often when an agency visits an institution for the first time, it concentrates on program contents in their technical aspect or in their pedagogy: number of hours of science teachings, good quality of staff…There are so many important criteria in engineering education today such as new pedagogies, internationalisation of students, numerical aspects of engineering and for some of them, we are quite in societal problematics (use of "Big Data" in society is a problem of ethics).

It is during following up visits that the agency begins to have a look everywhere and especially on criteria more specifically linked to society. It is completely normal that an institution that does not fulfil basic requirements concerning engineering education, even if criteria linked to society are fulfilled is not accredited because the agency is there at first to verify the quality of the institution.

However, the trend is now to have simplifications in the follow up audits: this is a danger that agencies that are taking into account society preoccupation do not take them into account them anymore.

2.3 Role of the socio economic member or experts

They are necessary

More and more quality agencies have socio economic members or experts in their audit panels because it is necessary to understand precise things about employability of the institution for example and that those people coming from society are qualified to deal with this part of the criteria. Either they are in their working position facing those debates or their company has realised studies on them [3].

But not sufficient

Employment of "socio economic" members can hide a great diversity among those people and some of them can be less conscious of a specific societal problem that sociology teachers for example. However, very often sociology teachers are not member of agencies! So this is not the unique solution: if people have no occasion to discuss together between academic and socioeconomic people, as well during CTI 's meetings (such as expert formation) as well as during audits, it is a pity so, it is a very important thing to have exchanges between different categories of members.

Very often, the agency employ specific experts on a specific field, for example in CTI we have experts in innovation, in SD and in health and security at work that help CTI in its demarches such as analysing the "focuses" that will be explained later on.

3 THE IMPORTANCE OF THE LEARNING OUTCOMES APPROACH

For some years, companies (such as Boeing in the early 90's [3]) and now many agencies ask the institutions to describe their programs in terms of learning outcomes, this is particularly specified in EAFGS [4] and in R&O [5] but also in CEAB [6].
A good comparison on those subjects by GEDC can be found in [7]. This presentation in terms of skills really allows preoccupations of the society to be taken into account.

3.1 It allows to take into account the needs of society as criteria

The learning outcome descriptions allows the introduction of specific skills expected from the graduates. For example, in CTI's learning outcomes (among 14 at the total), the second chapter concerns the adaptation of graduates to the constraints of companies and society:

1. The ability to take into account the issues of the companies
2. The ability to take into account the issues of relations at work, ethics, responsibility, safety and health at work
3. The ability to take into account environmental issues
4. The ability to take into account issues and needs of society

These demands are very clear and precise; they constitute a specific paragraph that completes two other ones: the first one concerns the acquisition of technical and scientific knowledge and the mastery of their implementation and the last one is about organizational, personal and cultural dimension of engineering education

3.2 This can be also done through guidelines

For criteria of agencies common to a set of countries, reasons may occur that make things not completely explicit. For example, the first look at learning outcomes in EAFSG shows nothing about preoccupations of society, we have very common basic engineering requirements:

Knowledge and understanding; Engineering Analysis; Engineering Design; Engineering Practice; Investigations; Making Judgments; Ability to engage in Lifelong Learning.

We discover that inside the detailed items (guidelines) that define a criterion, we can find societal preoccupations; we must carefully look to be sure of the content of those criteria in front of those of CTI [4].

Inside "Investigations" we find: "Ability to consult and apply codes of practice and safety regulations"

Inside "Engineering Practice" we find: "Critical awareness of economic organizational and managerial issues"

And Inside "Engineering Analysis": "Ability to identify formulate and solve complex problems"

It is clear that the problems of society are considered by EUR-Ace but not at the same intensity (only guidelines) as by CTI.

4 AS AN EXAMPLE: THE CASE OF CTI

4.1 The partner's context of CTI

ENQA asks all its members to make their requirements evolve through concertation with stakeholders. In the network of close partners of CTI, 3 organisms exist that have particular missions and preoccupations on some precise subjects linked to society:

CGE (Conférence des Grandes Ecoles) is an association of Schools of Management and Engineering. It has for many years created a commission on Sustainable development and Social responsibility, CTI members had meetings with this commission, in 2010 we first defined common principles that were not at this moment part of our criteria but only recommendations to schools. Then in 2014 they began part of the criteria.

INRS (Institut National sur les Risques et la Sécurité) is an organism linked with the French Public Welfare System, its role is to study risks in all professions. From about 10 years it intervenes in Engineering Education Institutions to explain risks, professional diseases (one of them being burn out), and their prevention. CTI has realized an enquiry on fresh graduates together with them. In 2016 criteria linked to Health and security at work were part of CTI's criteria.

The interest for innovation and entrepreneurship has been awaken in CTI through many influences: first the researchers in academic part, then the socioeconomic members but also the French Government with the PEPITE device. Some HEIs had a strong interest for it since a long time but the creation of PEPITE made things evolve massively.

These three points were considered by members of CTI as common strong and necessary points for education of engineers in link with evolution of society. So, in 2016 CTI decided they should become part of its criteria.

4.2 The criteria associated

CTI has evolved a lot in taking account society needs between 2006 and 2016: a recent comparison in [13] show a change of paradigm in the description of its criteria. In the learning outcomes approach main criteria are specified (they are developed in 2.1) but it is not sufficient. It is also necessary to insure that the management of institution is in conformity with the learning outcomes expected from graduates. This is very important because institution should be considered as a model by its students.

In February 2014, CTI, considering that teaching social responsibility to engineers was a critical aspect for society and a duty for engineering institutions, decided to include immediately SD not only in the intended learning outcomes but also in the description of the global policy of the institution: this was an important evolution of the accreditation criteria.

The strategic guidance document of the institution being evaluated must include the orientation chosen by the institution regarding SD and particularly the Green Plan that describes the institution's strategy and its implementation and evaluation. The strategic guidance document is an important part of the self-assessment report because the institution's administrative council votes it, and when this institution is part of a group of faculties the university council votes it too.

CTI wishes strongly that institutions really integrate SD through curricula in the education of engineers but also apply the principles of SD in their own management, working in an exemplary way.

When an institution is accredited or reaccredited, the implementation of Green Plan has to be explained within the quality process of the institution.

CTI has quoted 8 axes of operational actions to be verified during the evaluation process: strategy and governance, social management and local integration, environmental management, research, curricula, documentation, industrial rooting, quality management and continuous improvement

CTI also stresses that a specific innovative active pedagogy has to be put in place for SD: the pedagogy of action puts the engineering student in the situation of finding and building solutions to "real world" matters. CTI specifies that the recruitment of students must guarantee diversity according to a policy concerning chance equity [7].

4.3 The focuses

It is not easy to introduce new criteria in an old system of reference and to be sure that they will be taken into account.

We decided to create "focus", that is to say that in the self-evaluation report, the institution has to present in four pages one of these new specific points. In this way it is easier to convince those (members or institutions) reluctant to change and it will be also easy to publish a document showing the state on a subject inside institutions and giving ideas to institution that don't have: a best practice catalogue. So, this year CTI asked more information on those 3 points that seem important for society at this moment:

- Sustainable development and social responsibility
- Health and Safety at work
- Innovation and Entrepreneurship

Among the institutions that were concerned by periodic evaluation (about 30 this year) one third were submitted to the redaction of each focus. That is to say that we collected the view of 10 institutions on each subject. In February 2017 each of the focus was analyzed and the conclusion presented to all deans.

Institutions and CTI members found this exercise very interesting, a debate was hold at February 2017 conference and results published, then the members of CTI decided, on the same themes, to go on with these focuses to get a more important panel (there are 206 institutions for Engineering education in France).

So we think that those points can now really be considered as part of a quality system: accreditation system can help institution to progress on society subjects.

5 CONCLUSION

The point of introducing criteria linked to society is important but not so easy: it was possible in France because periodic evaluation took place already 3 times before (3 periods of 6 years since 1997) and quality of institution had increased; but now, we are trying to simplify accreditation procedure so "details" will be suppressed: it show the importance that these factors be considered inside criteria and not in guidelines.

Is it possible to define priorities into criteria? We observe that very often in many countries doors of the accreditation criteria are opening to society problems: the importance given now to soft skills and transversal skills is a good attempt.

However, we think that it strongly depends on the law of the country and on the political situation (emphasizing or not such or such problem), however, in this case, the public opinion has a role to play in the criteria chosen for education realising pressure on the agencies.

We can conclude saying that consideration of engineer's education preoccupations linked to society has much evolved since 10 years, because both of society and companies but this has still to progress in some countries. These preoccupations must be taken in consideration either in law or in another place, but accreditation agencies when existing stay a place very convenient for this.

Continuing Engineering Education and Lifelong Learning

Part-time Engineering Master Programmes: Implementing Real-life Engineering Problems as a Means of Learning.

B. Nørgaard
Lecturer
Aalborg University
Aalborg, Denmark
E-mail: bente.@plan.aau.dk

For more than two decades, University Aalborg has enrolled learners into their part-time engineering Master's programmes. These programmes are designed for employed learners who work full-time in the industry and who want to keep their job while they study on a Master's programme. Aalborg University's pedagogical approach is solely based on problem-based learning, which means that learners are, to a large extent, implementing real-life engineering problems as a means of learning. This paper will investigate what types of problem formations the learners are able to identify from their working-life, which is also aligned with the requirements of the part-time master's study programme.

Conference Key Areas: continuing engineering education and lifelong learning

Keywords: continuing engineering education, problem based learning, problem formations

INTRODUCTION

For more than two decades, University Aalborg have enrolled students into its part-time engineering master's programmes. These programmes are designed for employed learners who work full-time in the industry and who wish to keep their job while they study on a Master's program. Consequently, the courses and seminars are mainly given in the evening and during weekends.

The part-time Master's should not be mistaken for the traditional Master's of Science (MSc) programmes, which according to Bologna is two years of study (120 ECTS) following a Bachelor's degree. The part-time Master's programmes are specially prepared to meet the needs of employed learners who lack knowledge, skills and competence within exact identified areas (subjects). The curriculums are carefully designed to be attractive and exciting for the engineers and they provide an opportunity to work with authentic problems from the learner's professional life. Thus, the Master's programmes are 60 ECTS, of which at least 30 ECTS of the programme content is project-work and the 30 ECTS are subject courses or seminars. The extensive amount of resources dedicated to project work allows the learners to identify, analyse and solve real-life engineering problems in-depth.

This paper will investigate what types of problem formation the learners are able to identify from their working life, which also is aligned with the requirements of the part-time Master's study programme.

1 THE MASTER'S PROGRAMMES

The Master's programmes at Aalborg University, to a large extent, implement real-life engineering problems as means of learning. This concept of 'posing problems' as a means of learning began in the 1960s when Paulo Freire described '*the banking concept of education'*, which is still prevalent as '*education becomes an act of depositing, in which the students [learners] are the depositories and the teacher is the depositor'* (Freire, 2009 p. 72). This educational approach, with the teacher as narrator of a subject and learners listening to memorize the narrated content, is something that we are all, to some extent, familiar with. But, as Freire (2009) argues, this teacher-centred approach must be rejected: '*they must abandon the educational goal of the deposit-making and replace it with the posing of the problems of human beings in their relations with the world'* (Freire, 2009 p. 79). Abandoning the banking concept and implementing the posing of problems is one of the backbones of problem based learning (PBL) and, hence, the problem-orientation and problem formations. Another pioneer in the field of 'posing of problems' was Howard Barrows, who in the late 1960s was involved in the early stages of the development of PBL at McMaster University in Canada. Barrow defined the concept in terms of specific characteristics as being student-centred, taking place in small groups with the teacher acting as a facilitator, and being organised around problems (de Graaff et. Kolmos, 2003, p. 657). In Denmark, the PBL model was developed based on ideas from, among others, Illeris, *'who formulated the principles of PBL as problem-oriented, project work, inter disciplinarily, participant directed learning and the exemplary principle and team work'* (Kolmos et al., 2004, p. 10).

At Aalborg University, all of the students and academic staff act out the basic principles of PBL, which is a general characteristic of all of the studies at the university. The principles, which are acknowledged by Aalborg University, are:

- Problem-orientation: Problems/wonderings appropriate to the study program serve as the basis for the learning process.
- Project organization: The project stands as both the means through which the students address the problem and the primary means by which students achieve the articulated educational objectives. The project is a multi-faceted and often extended sequence of tasks culminating in a final work product.
- Integration of theory and practice: The curriculum, instructional faculty members and project supervisors facilitate the process of connecting the specifics of project work to broader theoretical knowledge for the students. The students are able to see how theories and empirical/ practical knowledge interrelate.
- Participant direction: Students define the problem and make key decisions relevant to the successful completion of their project work.
- Team-based approach: A majority of the students' problem/project work is conducted in groups of three or more students.

- Collaboration and feedback: The students use peer and supervisor critique to improve their work. The skills of collaboration, feedback and reflection are an important outcome of the PBL model.

(Barge, 2010)

On the part-time Master's of Building Physics programme, which has been selected for this study, the PBL principles are well integrated into the study. The Master's of Building Physics is a research-based education programme that enrols researchers and leading experts in the field, and which applies current scientific theories and methods to practical building-related issues.

This Master's is an accredited, qualifying continuing education programme, which is aimed at all professional groups with a long or intermediate higher education in the field of construction, such as:

- Civil, diploma and academics engineers;
- Building engineers; and,
- Architects.

In addition to a relevant higher education, it is required that the learner should have at least two years of practical experience at a high level of construction. This practical experience enables the learners to bring real-life problems with them into the Master's programme, which will be exemplified in Section 3.3.

2 RESEARCH APPROACH

The research approach in this study is basically a literature review of PBL, with a particular focus on problem formation, and a review of the Master's of Building Physics programme that has been selected as the subject context for this investigation. The literature review is expanded by empirical data that consists of problem formations, which are compiled among the Building Physics learners, demonstrating their ability to identify authentic problem formations within their everyday professional work and applying it as means for learning through their project work.

This paper will begin with a theoretical definition of problem formation in a PBL environment. It will then describe the Master's of Building Physics programme (curricula and semester description). Next, some examples of the student's problem formations will be given (i.e. research questions). This paper will then conclude with a discussion of the learners' opportunity and ability to draw real-life problems as a means for learning within the subject context of their study programme.

3 PROBLEM FORMATIONS IN PART-TIME MASTER'S PROGRAMMES

Aalborg University's pedagogical approach is solely based on the educational concept of PBL, which means that all of the students and staff enact the basic principles of PBL, including the part-time engineering Master's programmes. They are designed according to the Aalborg PBL principles; that is, they are problem-based and project-organised. The learner's collaborate in teams, applying theory and practice to solve real-life engineering problems.

The use of problem formations as means for learning and problem-orientation is one of the pillars of the Aalborg PBL model. In relation to the Master's programmes, problem-orientation becomes even more applicable since the learner's are professionals with a working-life and practice, from where problems can be identified. From a learning perspective, the context of the problem has to be as authentic as possible. If the context is the learner's workplace, then the criteria for relevance must be met. Another observation that speaks for problem-orientation in continuing engineering education is the fact that '*53–88% of the participants in continuing educations are adults who are work-related motivated'* (Lorentsen et al. 2010). The learner's are work-motivated and this may support problem-orientation; hence, the learner experiences work-related qualifications and benefits.

3.1 Problem formations from a theoretical perspective

There have been many academic discussions about 'what is a problem'. Overall Kolmos (2004) argues that definitions of problems are diverse in different professional areas. Quist (2004) has, from a literature review of diverse problem formulations, located a variety of understandings. Basically, there is consensus that a problem can be initiated by a w*ondering, a problematic situation* (Quist, 2004; Guerra & Bøgelund, 2014) or an *un-explored potential* (Guerra & Bøgelund, 2014 with reference to Borrows & Tamblyn, 1980; Quist 2004; Jonassen, 2011).

- A wondering: This indicates an observed phenomenon creating (qualified) curiosity (Quist, 2004), which can include situations, events, persons or a thing (Guerra & Bøgelund, 2014), something that happened or happens, something heard and seen (Quist, 2004), an uncovered need or wish (Guerra & Bøgelund, 2014; Quist, 2004).
- A problematic situation: This can, according to Quist (2004), be 'something you find a scandal', 'a lack of knowledge' or 'a lack of function' and it can be caused by contrasts; that is, between a wish and reality, conflicts, contradictions (Guerra & Bøgelund, 2014; Quist, 2004). In the definition of a problem, Guerra and Bøgelund (2014) explain the understanding of a problematic situation as also including the student's sorrow and/or indignation, frustration or stress, which makes them act to change this problematic situation.
- An un-explored potential. This idea is also a possible starting point for the problem formulation, such as the potential of a mobile phone not only as a device for communication but also to take photographs and video, agendas, e-mails, GPS applications and so forth.

Furthermore, consistent with the Aalborg PBL model, problem formations can be defined as theoretical, practical, social, technical, symbolic-cultural and/or scientific (Barge, 2010, p. 7). Depending on the type of problem and its starting point (a w*ondering, a problematic situation* or an *un-explored potential)* there is also a distinction between 'retrospective' or 'prospective' problem formulations (Holgaard et.al. 2015, p. 37), which can be characterised by:

- Retro-spective problem formations want to find justifications and explanations for something already happened;
- Pro-spective problem formations are designed to solve practical problems and to produce concrete solutions

In summary, problem-orientation, or problem formations, as one of the basic principles of PBL, cannot be described and categorised as one and only type of problem. Problem-orientation is a concept that relates to various different types of problem formations with different points of departure, implementing distinctive theory and methods that are the means for solving the problem and which are documented by the learners in their project work.

3.2 The part-time Master's of Building Physics programme

The Master's of Building Physics programme has a background in two urgent challenges of social significance:

- More than a third of the total Danish energy consumption goes to the heating of buildings. To realise the goals set by the EU and the Danish government to reduce CO2 emissions, it is imperative to significantly reduce the energy consumption of buildings.
- More than half of all building damage is caused by damp, such as in relation to energy efficiency and post-insulation. Many of the damages arise due to lack of knowledge or errors in design or execution. This results in an increased risk of damp accumulation, which may cause mould and poor indoor climate, and—in the longer term—degradation of materials and constructions.

Large energy savings in the construction industry can be difficult to achieve—both in building engineering, economic and cultural terms—and the damp-sensitive consequences result in additional complexity. In view of these challenges, there is a need for a competency lift among several professional groups in the building and property sector.

Building Physics Curriculum

Title: Master's dissertation of Building Physics
Module descriptions for the 4th semester

The Master's project is written within the building area and contains a presentation of previous research in the field and the Master's project relation to this.

Learning ou tcomes

Knowledge
The student must have obtained:

· In-depth knowledge of one or more selected subject elements.
· Wider insight into the field as regards theories and methods, as well as their mutual context, possibly in connection with a renovation or new-building project.

Skills
The student must have the following skills:

· Independently, systematically and critically identify, formulate and analyse the current problem formation.
· Relevantly relate the problem formation to the subject, including explaining and justifying the choices made in the delimitation of the problem formation.
· Relate the subject of the project to a historical context.

Competences

The student must have obtained the following competencies:

· Independently take and justify the choice of scientific, theoretical and/or experimental methods.

· Independently and critically evaluate the chosen theories and methods, as well as the project analyses, results and conclusions.

· Communicate relevant academic and professional aspects of project work in a clear and systematic way.

These are the goals for the learners and they should be followed throughout their Master's dissertation to demonstrate that they have achieved the defined learning outcomes, which is ranked in knowledge, skills and competences and which will be the basis for the assessment.

3.3 Cases

With a background in the two urgent challenges that have been identified (i.e. the need for energy savings and damp-sensitivity in construction), the learners have identified the following problem formations for their Master's dissertations.

Case 1: In-door damp insulation of an older brick-build basement: a case study and theoretical analysis of mineral insulation panels
How do the different types of insulation plates react to each other and does it matter what type of surface treatment is used?

Case 2: Bathrooms instead of back stairs: the conditions for establishing bathrooms in an existing back staircase
What are the damp conditions in a shared bathroom in a basement, bedroom with shower cabinet and existing back stairs?

Case 3: The thermal and atmospheric indoor climate in offices
What is the relationship between the measured and experienced thermal and atmospheric indoor climate in a number of offices in the City of Rødovre and the City of Copenhagen?

Case 4: Calculated energy versus measured energy consumption
How big is the energy requirement that is calculated in connection with the design of the building in relation to the energy used when the building is constructed and in operation?

Case 5: A study of the options for in-door climate and energy renovation in primary schools
This project examines whether or not there is a correlation between energy consumption (in terms of energy labels of the building) and the poor indoor climate in the public schools in Denmark?

On the basis of the problem formations, it is, of course, not possible to tell how well the learners have managed to meet all the learning outcomes outlined in the curriculum. However, it is possible to see if the problem formations are aligned with the topic of the semester and what type of problem formations the learners are able to come-up with.

4 DISCUSSION

This paper presents five different examples of Master's dissertation problem formations, which were randomly selected within the Master's of Building Physics programme. As the examples demonstrate, the learners identified innovative and real-life problems from their respective employment. Even though their backgrounds and jobs are very different, they all managed to draw up problem formations from their professional life, which also match the programme of study of the Master's of Building Physics.

The five problem formations were identified within the same study programme (curriculum) but they are diverse due to the different professional areas that the students worked in (Kolmos, 2004). The problem formations case 3 *'What is the relationship between the measured and experienced thermal and atmospheric indoor climate in a number of offices in the City of Rødovre and the City of Copenhagen?'* and case 4 *'How big is the energy requirement that is calculated in connection with the design of the building in relation to the energy used when the building is constructed and in operation?'* and case 5 *'This project examines whether or not there is a correlation between energy consumption (in terms of energy labels of the building) and the poor indoor climate in the public schools in Denmark?'* are all problem formations that can be identified as 'a wondering' since the learners explore phenomena which creates curiosity that can be disclosed. They can also be identified as retrospective projects because they seek justifications and explanations in regards to the phenomena. The problem formation case 1 '*How do the different types of insulation plates react to each other and does it matter what type of surface treatment is used?'* can be categorised as 'a problematic situation' because the project explores a lack of knowledge within different isolation plates and in their use. The problem formation is also designed to solve a practical problem, which is characterised as a prospective project. This is also the case for the problem formation case 2 '*What are the damp conditions in a shared bathroom in a basement, bedroom with shower cabinet and existing back stairs?',* which produces a concrete solution to a practical problem. However, the problem formations can be identified as 'an un-explored potential' because the project explores the conditions for establishing bathrooms in a back staircase.

This analysis, of the five problem formations reveals their differences. Even when identified within the same curriculum, the diversity is clear. Nevertheless, they all are 'discipline projects' (Kolmos et al. 2008) because the method, discipline and subjects are given beforehand and the learners have chosen the subject within a rather narrow area of building physics.

Additionally, only one of the selected problem formations has been completed through group work (two learners). The other four have been completed by individual learners, which compared to Aalborg University's ordinary Master's students (MSc) is a high share of individualists. This might be due to the real-life problem formations: the learners are work-motivated and want to explore their 'own' professional practice and context.

The five selected problem formations reflect the learners' ability and shows that they are able to identify real-life problems within the frame of the Master's of Building Physics curriculum. However, the learners have identified diverse problems due to their different professional contexts and practice.

5 CONCLUSION

In this paper, the part-time Master's of Building Physics programme was presented as a case for the analysis to answer the question '*what types of problem formations are learners able to identify from their working-life. It will also ask if this is aligned with the requirements of the part-time Master's study programme.* In conclusion, the analysis shows that the learners have ability and they are able to identify real-life problems within the frames of the Master's of Building Physics study programme. The problem formations are all aligned with the two overall identified topics of the semester: the need for energy savings and damp-sensitivity in construction. However, this rather narrowly identified topic leads to 'discipline projects' through which the problem formations are solved. When it comes to '*what type of problem formations the learners are able to identify'* this case shows that the five random selected problem formations are initiated by a wondering, a problematic situation and an un-explored potential. These three understandings of problems are represented in the case and they are retrospective and prospective perceptions of the problem formations. The diversity of the problem formations reflects the learners' work-related motivation because the problem formations are all initiated by their professional practice and context.

ABSTRACT

Lifelong learning is a key factor for the development of a sustainable workforce. Recognized qualifications, such as engineering, alongside with transversal skills enhance individual employability. The authors aim to explore the rationale of one out-of-school and hands-on program, Project 4x4InShools (4x4IS), as one of the pillars for the development of engineering and technical skills aiming to develop a positive vision of industrial and technical careers. The long-term objective is to raise awareness and knowledge of industry, industrial processes and its impact on everyday life towards industry and future engineering or technical career development. Namely careers in the metalworking sector or related industrial clusters. 4x4IS it's an international project with countries from five continents. This paper will focus on the Portuguese experience that encompasses youngsters from 15-18 years.

The lack of qualified industrial technicians and engineers, and consequently the lack of a qualified workforce has been on the agendas of governments worldwide. This issue gets more pronounced since Europe faces an aging workforce. This work rests on the belief that the promotion of technical and industrial skills is an important tool for vocational education and lifelong learning in consideration for sustainable development practises. The "new" industry must compete by adding value to industrial processes and products. These assets are made possible by innovative engineering and countries with innovation inputs related to human resources training and development (engineering education) directly linked with higher competitiveness standards. Thus,

4X4IS main objective is to bring youngsters closer to industry, believing that everyone can make a difference for individuals, countries and economic prosperity.

Conference Key Areas: Attractiveness of Engineering Education, Skills and Engineering Education, Continuing Engineering Education and Lifelong Learning

Keywords: Lifelong learning, Sustainability, Project 4x4IS; Industry

INTRODUCTION

Nowadays youngsters (their educational tutors and other stakeholders) have negative images and perceptions of the metal industry and industrially related careers, that tend to be dirty, heavy, noisy and physically exhausting. According to this global ecosystem, industry related careers, up to here, were not socially valued and were unattractive to young people searching for a future profession. It is recognized that the industrial sector is unable to inspire and motivate enough young people to enter engineering programs or technical training paths related to industry. Future predictions show a significant fall in meeting business and industrial needs [1 - 5]. According to previous studies youngsters' tend to choose "easier" paths and careers with another public image and recognition [6]. Various researchers have studied students' attitudes towards "industry", "science" and "technology". Researches show that youngsters often have stereotypical images and that those images impact their attitudes toward science, industry and technology [7-16]. It appears that if a youngster can see himself/herself in a career, then, the likelihood of that person persecuting an educational program to prepare him/her to that career increases [17].

This diminished interest in engineering, industry and industrial related careers has been long associated with several factors such as: perceptions and images of industry, lack of knowledge, lack of understanding the contribution of engineering for everyday life, teaching methods, curricula, mismatch between values and the way technical subjects are approached, career guidance, youngsters lack of understanding and appreciation for their potential future role in society [18-23].

"Young people need to see the point of it all. They especially want practical application (not just practical work). This might be learning about a job, developing personal skills, experiencing team work or having a subject explained to them in terms of its contemporary context" [23, p.2]. Youngsters need these divergent approaches to learning versus most schools' curriculum approaches. It's unquestionable that lifelong learning with all the associated strategies are central issues for the development of a capable workforce and productive countries.

The Royal Academy of Engineering predicts a shortfall of 200,000 qualified engineers in the UK by 2020 [24]. The skills shortage [1] is an ongoing challenge for the project. The project 4x4 in Schools addresses this issue and builds the skills and talent of young people aiming their future career paths.

1 THE PROJECT 4X4 IN SCHOOLS

1.1 4x4 in schools

The Jaguar Land Rover's 4x4 Global Challenge is an annual competition for 11-19 years' olds to design and build a radio-controlled, four-wheel drive model vehicle that features Land Rover's all-terrain characteristics. Over the course of a school year, students research, design and manufacture their vehicle, and perform tests before they compete with teams from other schools at the competition stage. Jaguar Land Rover (JLR), and international partners provide guidance and support throughout the process, including visits to participants' schools and youth groups. An average of 116,000 young people participated in the challenge each season starting on 2015/16.

In the last semester of 2015, JLR launched the Land Rover 4x4 in Schools programme globally in partnership with various in-country coordinators, including Portugal. Teams from countries as far afield as Australia, United States of America or South Korea competed in their national challenge competitions and the best teams from 15 countries meet every year for the World Final.

The 4x4 Challenge is operated in partnership with the Institution of Engineering and Technology (IET), JCB Academy (JCB), Science, Technology, Engineering and Mathematics Education Coalition (STEM), DENFORD and several leading engineering and education organisations. Young people participating in the scheme can be accredited for their achievements through schemes such as CREST, ASDAN and the Duke of Edinburgh Award and the Arkwright Trust.

The base for the program design is the creation of an ecosystem that potentiates capabilities and competencies toward future industrial careers, anchoring strategies on collaborative learning, active learning [25-32] creative thinking, project based learning, among others.

1.2 4x4IS objectives

- The challenge is educational but also provides participants with the opportunity to experience something that is realistic, as well as relevant to the operations within industry.
- Provides an experience where students can develop and embed knowledge and skills which may be later required in further education or their chosen career.
- Is motivating, exciting, challenging and fun for both the students and adults involved.
- Provides young people with the opportunity to work as part of a team or independently to develop problem solving skills and techniques.

- Enables real-life engineers (STEM Ambassadors) to connect with the future of the industry by sharing their engineering knowledge, expertise, enthusiasm and commitment with students from a range of backgrounds.
- Provides an opportunity for students to learn and develop through participation in a hands-on practical experience.
- Enables young people to gain understanding and awareness of what engineering is, encouraging them to actively think about a technical career.
- Integrates subject knowledge from key areas of the curriculum with the wider agenda of work-related learning, enterprise, key skills and personal development.
- Enables young people to be recognised for their achievements through schemes such as CREST, ASDAN and The Duke of Edinburgh Award.

1.3 4x4IS activities

The teams have access to several support resources, such as on-line support or a designated JLR tutor, 3D engineering software, computer numerical control machines (CNC), 3D printing machines. There are well defined rules for the competitions (either regional, national or world) that the teams must comply if they want to attain with the purposed objective. The teams must take in account several items when designing, developing and materializing their projects:

1. Each team must contain a minimum of 3 to a maximum of 6 students, each one with defined roles (e.g. Team manager, marketing manager).
2. Use Computer Aided Design (CAD) software to produce their ideas and model it in three dimensions (3D).
3. Use several manufacturing technologies to produce their own 4x4 vehicle.
4. To manufacture the body shell each team must choose either to use technology available at the school/college or at a real manufacturing company as a sponsor.
5. Follow the specifications concerning several rules, each car body must have some electronic features such turn lights when the environment is dark, tilt sound when the vehicle has a lateral inclination.
6. Produce a design folder including initial ideas; design development and evidence of the developed work, maximum 20 pages (A3 size).
7. Develop partnerships. 4x4inschools teams are encouraged to develop partnerships and seek assistance from academic, businesses and industry throughout this engineering process. However, all aspects of this engineering and industry partnership should be represented in the team's portfolio. This includes CAD designs, electronics, and the creation/production of the portfolio, which should remain the responsibility of the students in the team.
8. Prepare and deliver a 10 minutes' verbal presentation on their work with or without visual aids.
9. Learn all skills by self-learning methods or by seeking help from partners referred in item.

Fig. 2: 4x4inschools track

For the youngsters' teams these are complex projects, for so, they are reminded about some considerations such as:

- Resources: CAD/CAE packages help them to draw and to develop their ideas in 3D. As with most drawing packages, it takes time to learn how to use the software. CNC and 3D printing machines allow youngsters to see the project take "body" but the technology use must be studied and applied with caution. Wind/smoke tunnels allow youngsters to see the scientific aerodynamic principles and test them.
- ICT tools: the resources used are complex, and so are the results to be achieved, and the ways to support self-learning. ICT tools allows youngsters to manage their time and learning in more efficient ways. They can communicate and share doubts, help each other, have access to privileged material, and see real case studies, alongside with the JLR tutor support.
- Research: Teams are asked to investigate existing 4x4 car designs to find out the latest developments occurring in the world of 4-wheel drive design. Concentrate research on areas that could help teams, for example, gears, car body shell design, and try to apply the principles to the team ideas and in-hands projects.
- Testing: teams may want to consider testing a variety of car designs, or car parts to evaluate their performance in pass the obstacles.
- Manufacturing considerations: Rookie teams' have access to a beginner 4x4inschools Kit which is constituted by simple radio-controlled vehicle, but teams need to change at least the body shell and upgrade the electronics. Professional teams can build their own vehicle from zero.

Fig. 3: World final 2016

2 THE PORTUGUESE EXPERIENCE

2.1 4x4 IS Portugal

The cooperation between JLR and the Portuguese Technological Centers started in 2015, and it was organized two national finals. The project was developed in a consortium and the experience was obtained from similar projects for sensitize young students for Industry and Technical careers and related study areas. The consortium is a partnership with eight Portuguese Technological Centers spread in the Portuguese territory, from north to south.

Until the beginning of 2017 the consortium organized two national finals where 14 teams participated each year. It was possible to promote several immersion sessions directed at high schools (42 schools) encompassing more than 45.000 students. For the season 22016/017 it's already ongoing work with 14 teams' ant its foreseeable to make aware of the project and its objectives approximately 120.000 youngsters.

For the season 2015/16 the challenge actively engaged 87 young people, 78 males and 9 females with ages from 13 to 19. More than 50% of those with ages between 15 and 16 years old. The global activities within the project encompassed 38.388 young students, for the season 2015/16.

Table 1. Season 2015/16 demographic data

Targets	Schools	Students	Aware
Planned	15	90	15.000
Reached	18	87	23.388

Table 2. Season 2015/16 students by age group

Age	%
13	3,4%
14	10,3%
15	10,3%
16	25,3%
17	25,3%
18	20,7%
19	4,6%

Every year since the beginning it has been organized a National Final with the aim of selecting the best team for representing Portugal in the World Finals. Depending on getting extra financial support or sponsorship, it could be possible to select a second team to go to the World Championship, and provide teams in the two levels of the competition (beginner and professional).

Since the first time the Portuguese teams faced the challenge the perceptions were very good from the different national and international stakeholders. The youngsters differentiated on the resilient way that obstacles were faced and dealt with – e.g. technical and economic. All international rules 4x4inschools for the selection of the best teams were applied in the Portuguese Final and in the World final. The teams have permanent support from JLR tutor, technological centres, schools and teachers, among others, to manage their efforts during school time and free time aiming to the accomplishment of the project objectives without compromising academic achievement. As ongoing work the 4x4 IS Portugal team is conducting a longitudinal study, that started on the season 2015/16 aiming to assess perceptions and future training and development choices along with professional paths.

3 CONCLUSIONS

4X4 in Schools self-learning approach, supported by JLR and in-country partners, showed that it is very important for youngsters to apply their knowledge, skills and proficiency to tasks with an overall perceived meaning and using several different means (distance support, face to face meetings, collaborative work, sharing and developing knowledge through communities of practice) simulating as close as possible real industrial settings. And on the other hand, the contents and the final product with metal industrial relevance make youngsters aware of the impact that individual skills have on a wider project development and the results.

The authors believe that youngsters individually and has a team can be “trendsetters” who set their own learning and development paths and strategies. This concept points to the importance of e-learning, with all technological tools provided, in informal and non-formal learning has a mean for individual and group skill development towards sustainable development.

Young students need to experience “scenarios” in a hands-on approach with active learning strategies, to contextualize opportunities that the Metal Industries, the car industry and the industrial sector in general can provide. Making the linkage of the importance of technical and industrial related paths not only to individual fulfilment but also for the promotion of a sustainable industry contributing for the re-industrialization and for prosper countries and/or regions.

4 ACKNOWLEDGMENTS

The authors wish to acknowledge the support of Engineering in Motion and Jaguar Land Rover. The project results would not have been possible without funding from the JLR ‘Inspiring Tomorrow’s Engineers’ Programme, and the Portuguese Technological Centres. This paper reflects the perspectives and experience of the authors.

Creating a Smart Learning Space:

Learning With and Learning From Student Generated Data about Learning

ABSTRACT

In a course from our Social and Human Sciences master program, students are taught the social and behavioural sciences of learning ("learning sciences"). Students also learn how to conduct social and behavioural research by collecting data on campus during semester long projects. Proposed by internal "clients" from the school, the projects bring data on students learning both to teachers and to the institution, thus transforming the school into a lab for research and development on teaching and lifelong learning in science and engineering – a Smart Learning Space. This paper describes the design of this course together with examples of projects and their impact at different levels in the school. In particular, this course has laid the foundations for a culture of evidence-based and data-driven teaching and learning within the institution. We discuss the challenges we had to tackle as well as some perspectives for the future.

Conference Key Areas: Engineering Education Research, Continuing Engineering Education and Lifelong Learning

Keywords: Lifelong learning; Evidence-informed engineering teaching and learning;

INTRODUCTION

Engineers who graduate today will, in ten years' time, be working in a radically changed environment. Their ability to respond effectively will depend on their capacity to continue to learn and develop throughout their career. Hence, 'lifelong learning' has been identified as a key competence in engineering education [1, 2]. A second key issue in recent years has been the growing realization of the importance of evidence-informed teaching in science and engineering [3, 4] as well as more generally. An optional Learning Sciences course offered to Science and Engineering students has sought to address both these issues.

While the role of social and human sciences in engineering education is often ill defined, there is a clear rationale for including learning sciences and social and behavioural research skills within engineering programmes. Beyond the learning for students themselves, the data generated from learning research can inform educational decisions taken by learners, teachers and the school more generally, transforming the school itself into a teaching and research and development lab.

This paper will first outline the research base behind these concerns, will then describe the course and some of its outputs and will then look at its impact within the engineering school more generally.

1 RELATED WORK

Social and Human Sciences have been seen as a required component in the training of engineers for many decades [5]. Despite this fact, there remains a lack of clarity as to their role, with rationales offered including: (a) the development of personal qualities such as modesty, openness and creativity [6,7]; and (b) the development of 'professional skills' of working in multi-disciplinary teams, adopting ethical practice, being aware of social impacts and causes of technology, and communicating effectively in international and intercultural contexts [2].

Of any social scientific or humanities discipline, learning sciences has a particular and valuable role to play in engineering education. Lifelong learning has been identified as among the key 'professional' skills of engineers [1,2] and an ability to think about learning has been found to be associated both with increased attainment in formal education and with an increased ability to apply classroom learning to 'real-life' situations [8]. Learning sciences also plays a role in enhancing students' interdisciplinary competences since learning science is, by definition, an interdisciplinary space, drawing on neurology, sociology, educational psychology, information sciences, and anthropology. This mix of social, behavioural, and hard science disciplines provides a fertile space for engineering students to engage in the interface between disciplines. Studying how to research learning also provides practical skills in social research, while the ethical standards which apply in social and behavioural science research provide an opportunity to engage students in learning how to apply ethical principles such as self-determination, informed consent, vulnerable populations, as well as physical, psychological, and sociological risk.

Beyond these practical utilities for the learner, however, the study of learning sciences also provides an opportunity for the engineering school as a whole to become a learning organization. There is now clear research evidence that many commonly used higher education teaching practices are found to be less effective than underused alternatives such as collaborative learning, concept maps, use of visualization technology, use of conceptually-oriented tasks, and use of interactive teaching approaches [3,4,9]. However, although this research evidence tells us that some methods of teaching and learning work better than others "in general" (that is, they are "evidence-informed"), their implementation in particular contexts and settings will often depend on locally-collected evidence about effectiveness – an approach which is known internationally as Scholarship of Teaching and Learning (SOTL) [10]. Engaging in learning sciences research can provide this evidence.

The next section describes one attempt to do this, in practice.

2 THE SMART LEARNING SPACE

Within the social and human sciences strand of courses, a learning sciences course has been offered at Master level in Ecole Polytechnique Fédérale de Lausanne (EPFL) since 2012. The course has two goals: (a) introducing students to learning sciences research, with a particular focus on what it has to say about how they themselves learn, and (b) teaching skills of designing and conducting a piece of quantitative research on learning.

Around 60 students register for the course each year with 45 to 55 continuing to complete the research project.

In the first semester, learning sciences are introduced through interactive lectures and through a series of in-class experiments. These experiments mean that students are confronted with data about their own learning in different situations which ensures that the findings are integrated by students at a personal level rather than being seen as abstract representation of learners "in general". These classes also mean that students have an experience of how experiments and social surveys are actually designed. The experiments also generate real-life data which, in turn, is used in exercise/tutorial sessions by students to practice skills of social data analysis.

In the second semester, students use the knowledge and skills developed to carry out a research project, from the design phase to the reporting phase, in groups of 3 or 4. For the projects to be open-ended and realistic enough to provide an authentic and rich learning environment, project topics have to be research questions that can be answered with data collected locally. Students are assessed based upon a research report and a poster that they produce. In the first year of the course, students generated their own project titles, however from 2013 on, students were provided with a list of possible titles with each project being required to be (a) focused on learning and (b) of use to some stakeholder within the school (e.g., a teacher, other students, departments, or administrative units). Initially potential "clients" were largely sourced through personal connections by the teacher. Since 2014, the results of the student projects have been presented each year at a public poster session and again at the annual faculty retreat, and this has led to a growing interest in the projects within the school. In the academic year 2017-18 there are 13 different projects, with clients including teachers in Chemistry and Environmental Sciences, the school's Marketing, Gender Equality, MOOC, and Teaching Support units, the Library, and the Vice Presidency for Innovation.

The research that students carry out within the school, in turn, feeds back into the institution. It has helped teachers to test innovative teaching approaches and to validate their assessment methods. It has provided feedback on what Bachelor students have learned and where they struggle which, in turn, has allowed teachers to adjust their approaches to teaching and assessment. It has provided the school's pedagogic team with information about how students experience tutorials/exercises which in turn has allowed tutor training to be re-developed to better meet local needs. It has also provided data about learning which is fed back to students and which allows them reflect on and change their approaches to learning. In this sense, the course creates a virtuous cycle of individual learning, while producing data which allows for institutional learning. In this way, the whole school becomes a teaching and research and development lab in learning sciences. It is this idea that we refer to as the "Smart Learning Space".

Given that the research is being carried out by students who lack extensive training in learning sciences and in social research methods it is not surprising that the quality of their results can be variable. In many cases, however, the quality has been exceptional and a number of the studies have been presented by the students and the course teacher at international conferences.

3 RESULTS

Over the last five years, over 60 projects have been completed by students. While the projects have been diverse, a notable sub-set of projects has focused on the learning and challenges of our first-year students. Rather than present a random selection of different projects, a number of these projects which showed thematic continuity are presented in this section.

In 2014, one study compared exam grades from 236 first-year students with their score on an internationally normed test of conceptual understanding in classical mechanics called the Force Concept Inventory (FCI) [11]. The goal was to validate the course exam, and indeed the study showed that the exam did in fact test student conceptual understanding. However the data also showed that quite a few students who scored reasonably well when tested on their conceptual understanding still failed the exam. This data therefore made clear that, while understanding physics is a requirement for passing first-year courses in the institution, it is not enough [14].

One hypothesis to be explored as to the reasons for student failure was that the students were using inappropriate strategies in seeking to solve the problems. As Schoenfeld has noted, university exercises differ from those faced in high school in that high school exercises often require only the recognition of an exercise type and the application of an algorithm (called algorithmic exercises), while at university level exercises can often require the construction of an algorithm itself (referred to as problem-solving exercises) [12]. It was hypothesised that students were failing to recognise which exercises were simply algorithmic and which required actual problem solving. This idea was tested through a number of studies, looking at how students categorised mathematical problems [15], and through the use of a talk aloud protocol to explore the differences between student's self-reported problem solving approaches and their actual problem solving [16]. Further data was collected from a review of 136 first year student exams in order to catalogue the error types which arose most frequently [17].

The growing body of evidence within the school also prompted teachers to carry out their own studies. One, which focused on this question of student problem solving methods , also provided evidence that students who successfully identified an exercise as requiring a problem solving approach, and who understood how to apply such an approach, tended to be more successful in solving the kinds of complex problems posed in our first year exams [18].

Together, these studies provided convincing evidence that the difficulty for many of our students was not in their content knowledge, but in their methodological approach to problems and in their beliefs about such problems. This evidence has, in turn, led the school's Vice Presidency for Education in 2017 to adopt a strategic project on improving first year students' methodological skills in solving complex problems. This project draws on a number of strands including:

- A newly published book on problem solving and study skills for science and engineering students [19]
- A companion MOOC and learning companion website/app with in-build personal analytics to allow students to get direct feedback on aspects of their approaches to learning and problem solving
- An increased focus on modelling of and feedback on problem solving methods by professors
- A pilot project to assess the use of peer feedback as a tool in supporting students' learning of problem solving.

4 ISSUES AND CHALLEGES

While the impact and value of the course is evident, its development and implementation have not always been easy.

No resources have been allocated to the course since it started other than a single teacher who is responsible for managing teaching and experiments in a class of 60 learners and for overseeing between 13 and 18 projects each year. Resources required for gathering data, preparing posters, and for providing additional technical supervision and support for students have been begged or borrowed from supportive colleagues and units.

Secondly, ensuring that the projects were designed with an appropriate ethical basis was a challenge. Since the timeframe of the project was a single semester, students could not reasonably be asked to go through the time-consuming ethical approval process. At the same time, the projects needed to be ethical in their approach. The solution to this difficulty was to have a research protocol for the course pre-approved by the school's human research ethics committee which set a series of boundary conditions for the research projects. Students are required to demonstrate that their research design respects this protocol.

A third difficulty arises from the interdisciplinarity of the projects: students with training in mathematics, computational sciences, and machine learning are often able to apply sophisticated statistical and analytical techniques which are beyond the knowledge base of the teacher. This is an extremely desirable difficulty and demonstrates the exciting opportunities that arise in interdisciplinary fields. However it is also a challenge that needs to be carefully addressed in the assessment of the students' work. In such cases, clients have been invited to provide advice on the methods and techniques used, while the ultimate responsibility for grading rests with the teacher.

A more intractable difficulty arises from the dangers of over-taxing classes with data collection: thirteen groups of students each targeting the same population and each hoping to maximise their sample size has a danger of wearing out the goodwill of their fellow students as well as of the professors who are regularly requested to provide access to their classes. This difficulty does not have an easy solution, and has, on occasion, required active intervention on behalf of the course teacher to manage frustrations.

5 CONCLUSION AND PERSPECTIVES

As an interdisciplinary space that addresses lifelong learning and the transfer of competences from classroom to professional practice, which develops research and data analysis skills, and which addresses questions of social context and ethical practice, the arguments for learning sciences being available to engineering and science students are evident. Beyond this, our learning science course has created a context in which the whole school has been reframed as a teaching and research and development lab on engineering and science education – a Smart Learning Space.

The development of the course has not been easy. Lack of resources, ensuring ethical practice, assessing interdisciplinary work and avoiding friction within the school are all ongoing challenges to be managed. At the same time, the evident learning of students and the obvious value of their research to other learners, to teachers and to the school as a whole evident. Herbert Simon, both a renowned Computer Scientist and a Nobel Prize winner for Economics, once said that "Improvement in post-secondary education will require converting teaching from a solo sport to a community-based research activity" [13]. The study of learning sciences and learning research by students within our engineering school has provided an opportunity to build exactly this kind of community-based research on learning in our school.

ABSTRACT

The **ATHENS Programme** (Advanced Technology Higher Education Network/Socrates) is a 1-week exchange session, held twice a year (usually in March and November), by a network of 15 leading European technological universities. The Czech Technical University takes part in this programme since 2003. The case study of one of the courses, the Course on Application of Ionizing Radiation, is a subject of this paper. The course consists of 14 hours of lectures, 8 hours of experimental exercises and 3 hours of experimental demonstrations. The excursion into the Proton Therapy Centre and to the National Technical Museum is also included. This programme covers representative applications of ionizing radiation in various branches of human activities. In general, using radiation for diagnostics and therapy in medicine is more or less known to general public, however the course covers also the less known and discussed fields, as e.g. applications in geology and geophysics, art and archaeometry, and for analytical purposes. Some information about radiation protection and environmental radioactivity is also included. 20 students took part in this course in the March 2017 Session, from 8 universities. Except description of the course, the paper summarises also some feedback from students, which serves as the background for improving future runs of the course.

Conference Key Areas: Physics and Engineering Education, Skills and Engineering Education, Curriculum Development

Keywords: ATHENS course, application of ionizing radiation, course programme, feedback.

INTRODUCTION

The **ATHENS Programme** (Advanced Technology Higher Education Network/Socrates Programme) consists of 1-week exchange sessions, held twice a year (usually in March and November), organised by a network of 15 leading European universities of technology. The programme is aimed at carrying out intensive specialization courses, given at each member institution, enabling students to attend one of the courses offered by the network universities during 7 days. Since the groups of students are international, the language of the courses is English.The objective is to give students a brief immersion in another European education system. Each institution defines the number of credits given to its students participating in ATHENS courses (generally 2 or 3 ECTS credits, but some universities including CTU give no credits). Students are asked to evaluate the course they attended by filling an on-line evaluation form at the end of each Session. This experience, in many cases, gives students the desire to carry out studies of a longer duration (MSc and PhD levels) at an institution different from their home institution and thus facilitates exchanges between students of the major European technological institutions. About 60 courses are offered in each ATHENS Session.

The programme is coordinated by the ParisTech. It was established with the support of the European Communities SOCRATES Programme with annual subsidy from 1997-2001. Today, the Programme is mainly founded by contributions from the member universities. This is a disadvantage, as universities have usually limited and insufficient budgets all over the Europe and they do not cover full expenses to students (e.g., CTU covers about 60 % of living expenses and full travel expenses, if they do not exceed some limits given by varying distances to the destinations). The courses cover the wide spectrum of fields, mostly in science and technology, but they are also opened to arts and humanities [1].

Usefulness of this programme is out of any doubts. Science and technology are not the most popular disciplines among young people and any international programme at the good level can contribute to the attractiveness of studies at technical universities. And, moreover, such short time stays do not interfere substantially with study plans at the mother university, but they can bring an intensive view into a different country, a different university, a different branch of study and a different study system.

The Czech Technical University takes part in this programme since 2003. Its faculties offered the following courses for the ATHENS March 2017 Session [2]:

- Application of Ionising Radiation
- Text Searching Algorithms
- The PIV Method in Fluid Mechanics
- Management and Economics
- Introduction to Vibrational Spectroscopy
- Talent Management

The case study of one of these courses, the Course on Application of Ionising Radiation, is a subject of this paper.

1 OBJECTIVES AND STRUCTURE OF THE COURSE

The course is carried out by the Department of Dosimetry and Application of Ionising Radiation of the Faculty of Nuclear Sciences and Physical Engineering of the Czech Technical University in Prague. This faculty was established in 1955 in connection with starting the Czechoslovak nuclear programme, and though it added also some non-nuclear topics into its profile (mostly applied mathematics and non-nuclear parts of physics) during the years of its existence, it is still one of the strongest educational institutions in nuclear branches of science and technology in Europe. It covers practically the whole spectrum of nuclear and radiation theory, experimental practice and applications, having even its own small school nuclear reactor and its own small tokamak, both mostly for educational purposes.

The objective of the course is to obtain an overview of the theoretical and experimental background, concerning the application of ionizing radiation and radionuclides in industry and medicine. Depending on the mode of application, information is in most cases obtained through effects of radiation on matter. Detection and evaluation of radiation can give the desired information about these effects. The state of applications is described in lectures, but it is also implemented in the laboratory classes and experimental demonstrations.

The programme consists of:

A) Seven 2-hour lectures:

- Characteristic of Ionizing Radiation and Radioactivity
- X Ray Fluorescence Analysis
- Application of Ionizing Radiation in Geology and Geophysics
- Application of Radiation in Art and Archaeometry
- Radon-Problem in Radiation Protection
- Application of Ionizing Radiation in Medicine
- Personal Dosimetry and Radiation Protection

B) Four 2-hour experimental exercises:

- Polymer-gel dosimetry
- Spectrometry of Gamma Radiation with HP(Ge) Detector
- X Ray Fluorescence Analysis
- Personal Dosimetry - TLD

C) Two 2-hour experimental demonstrations:

- GOLEM - Tokamak thermonuclear installation
- Application of Ionizing Radiation in Medicine

As seen, this programme covers representative applications of ionizing radiation in various branches of human activities. Generally, using radiation for diagnostics and therapy in medicine is more or less known (though usually not from the point of view of physical principles) in general public, however the course covers also the less known fields, as e.g. applications in geology and geophysics, art and archaeometry, and for analytical purposes. Moreover, also scientific books about applications of ionising radiation (except applications in medicine and health physics) are not too frequently published. It is evident that it is not possible to cover all the issues connected with extensive use of ionizing radiation within a week, but the programme of the course can arouse students' interest in it, including links to the further educational literature for serious candidates.Let us bring at least two references for those, who want to make themselves more familiar with these issues, or for those, who want to follow us in our effort to extend knowledge of students in this field. [3, 4].

Some social activities are also included, mostly with the aim to make participants familiar with the city and the students' life. First of all, this is the orientation meeting during the first day of their stay, which gives to participants the basic information about the city and the university, and then some so-called European dimension activities: the Prague guided walk, the Prague discovery game, which is an unusual sightseeing in a form of a special game for groups, which ends by a dinner at a secret place, the Country presentations in the popular youth club, and finally, the Farewell dinner in the students' restaurant. Some of these activities are organised by our students from the CTU Student Union and from the CTU International Student Club.

As a part of the social programme, the excursion into the National Technical Museum was also included. NTM is one of the most popular and important museums in Prague and, after recent complete restoration and renovation of both the building and the collections, it is also one of the best technical museums in Europe. It is to some extent oriented not only to technology, but also to science [5].

The programme is intended for advanced students, who should be familiar withgeneral mathematics and physics at the level of standard courses at technical universities. Moreover, some knowledge of atomic and nuclear physics and of interaction of ionising radiation with matter is necessary.

Students receive copies of ppt presentations of all lectures and manuals for the practical exercises in advance. The course is finished by a written exam of 2 hours duration, which, however, is relatively simple and failure is very rare.

2 THE POINT OF VIEW OF LECTURERS

20 students (which is the maximum capacity due to the capacity of laboratories for practical exercises) took part in the course in the March 2017 Session, from 8 universities (9 students from the KU Leuven, 3 from the TU Wien, 2 from the École Supérieure de Physique et de Chimie Industrielles de la Ville de Paris, 1 from the Mines ParisTech, 1 from the Warsaw University of Technology, 2 from the Politecnico di Milano, 1 from the Universidad Politécnica de Madrid and 1 from the Technische Universität München). The main problem of these courses (not only of this one, but also of the other courses in the past and on the other topics) was that the participants were put together mostly by their interest on the topic. Though they all were from the top technical universities, they were as a minimum in the 4th year of study, and some knowledge of radiation physics was a necessary prerequisite, they had different background in physics and mathematics. This means that both lectures and exercises needed to be built on rather general explanatory level, to be understandable for all participants. On the other hand, we had not noticed any language problems, the level of English of all participating students was very good.

March or November dates of the courses, which are prescribed by the ATHENS Programme, are not too suitably chosen from the point of view of usual weather conditions. Participants may arrive on Friday and have a free weekend, which they can use for sightseeing. Prague is a very nice and interesting city, but these months are not the best ones for this purpose (on the other hand, this period is out of the main touristic season and Prague is not so overcrowded by tourists). However, the more important problem is that these dates coincide with teaching in the summer or in the winter semester, and therefore it is a bit difficult to harmonize the course schedule with the schedule of standard courses for our students. This difficulty not so much concerns the lectures, which is easier to organise, but finding space for laboratory exercises, which substantially contribute to the attractiveness of the course, is not easy.

And last but not least, organising and teaching in these courses asks for some enthusiasm of both teachers and students. As mentioned above, the ATHENS

Programme started with the support of the European Communities, which helped to prepare the structure of the courses and was a perfect starting motion. However, it is nowadays financed by participating universities and participants, which means that it operates with the limited budget, cheap accommodation for participants has comfort corresponding to the low costs, etc.

3 THE POINT OF VIEW OF STUDENTS

The feedback from students was obtained by discussion with them, and by a questionnaire they complete. They marked each lecture and exercise in the scale from 1 (the best) to 4 (the worst), which followed the old system of classification of exams before introducing the Bologna system and was fully satisfactory for this purpose. The mean value of such classification was mostly between 1.5 and 2, usually with slightly better values for exercises than for lectures. Surprisingly, the excursion into the Prague Proton Therapy Centre, the very modern medical installation, using the most advanced radiation therapy methods, which was included this year as the practical demonstration of application of ionising radiation in medicine, obtained relatively low rating (2,36). Possible explanation is the little pedagogical experience of a Center employee who accompanied the students and gave them an interpretation. General organisation and the level of course materials were also evaluated, the ratings were very positive this year (no mark 3 or 4, the mean values 1,24 and 1,28).

Students may also use this opportunity for verbal expression of their opinion. Unfortunately, this is sometimes readable only with difficulties, and sometimes the opinion of various students is self-contradictory, nevertheless it gives some more complex picture and feedback. Let us give some responses to individual lectures (without any order of importance and without any language corrections):

- A little too much material on some slides; some introductory theory (on slides, not orally) would be useful.
- Great material, maybe spend more time on this material.
- A little monotonous.
- Nice effort of interactivity.
- Too many examples of application.
- Out of interest field.
- Very clean and illustrative lecture.
- Out of interest but good lecture anyhow.
- It is sad that it comes on Friday morning.
- I am not interested in art, but I understand it is an important topic.
- Too much theory, more examples would be better.
- Too much applications and examples.
- Sometimes too much details.
- Interesting because of examples he brought.
- A lot of repetitive examples.
- Maybe he has to speak more quickly and increase the program.
- The first part (Technical) was good, but the examples were too many.
- Not enough detail, would be good to have more insight about diagnostic techniques.
- It was nice to have all the examples.

And some responses to practical exercises:

- Not much theory, chemistry explanations would be useful.
- A bit short in time.
- Theory is not well explained and much more complicated than we were told.
- Interesting technique, good assistant.
- The assistant did not look very enthusiastic.
- It was a pleasure to go to those practical exercises.
- Interesting, but not so many to do.
- We were not allowed to do much, not so interesting.
- I appreciate the professor. It was very funny.

About the visit in the Proton Therapy Centre:

- Lack of motivation and I did not understood at all the explanation, what is bad, because it would be very interesting.
- Nice centre and technology, but the guide was not skilled enough to attract the full audience.
- The guide could not explain it very well, otherwise it might be interesting.
- It was experience for my whole life. I was really interested!!!
- It was interesting to see the concrete implementation, but I would like to have more links with the theoretical aspects.
- Bad general explanations for the entire group from the guide.
- Interesting, but the guide was not passionate about presenting it.
- Maybe it is better to do a lecture before the visit.

As seen from these more or less randomly selected responses (however legibility of the hand-written comments played also some role in this selection), this survey, in which all participants of the course took place, gave the wide, though sometimes a bit contradictory view to the course. Some repeating comments to individual parts of the course should be used in preparing the next run. For example, some lectures were criticised for too many slides, too much text on slides or for too many similar examples of applications. There is no problem to reduce it. Revising and extending theoretical explanations of practical exercises would also be useful. Good relations of our department with the Proton Therapy Centre allow us to ask next time for some other expert from the staff for guiding and explanations. The problem, which, however, cannot be easily solved, is connected with differing interests of participants. They know the topics of the course in advance from the complete programme on the web pages of the ATHENS Programme, and if they claim in their responses, that they are not interested in chemistry, art or anything else, they must be reconciled with the fact, that these issues are mentioned. But it is possible to say, that in general the theoretical and practical parts of lectures, exercises and the course as a whole are well balanced.

4 CONCLUSIONS

The ATHENS Programme is a good example of activities, which liven up the “standard” university courses and extend the spectrum of topics taught in them with minimum time load for students. Nevertheless, they lose one week during the running semester at their university. One week stay at the university abroad is quite short time for making acquaintance with the university, the city and the country. However, it can awaken deeper interest in the university or in the topics of the course. Good quality is the necessary prerequisite of universities participating in this programme, and therefore, good quality of courses, lectures and students can also be expected.

The course on application of ionising radiation has been step by step improved according the responses of participants during the past years. Some improvements are still possible, as nobody and nothing is perfect, but we see that majority of students express their satisfaction with its quality. Moreover, the topics of the course are included into study programmes only at a few European universities. The Faculty of Nuclear Sciences and Physical Engineering of the Czech Technical University can take advantage from its more than 60 years long tradition in the field of nuclear sciences.

The ATHENS Programme is probably less known than some other programmes of student exchanges, especially as the ERASMUS Programme, and it is also less universal, being limited only to 15 participating technical universities. Its contribution to the European dimensions of engineering education is, however, non-negligible. And, said with some exaggeration, we are prepared to polish our course to full perfection.

The next ATHENS session will be held on 11-18 November 2017.

Teacher development in Massive Open Online Courses

Evaluating reflective practice in a sustainability MOOC

ABSTRACT

Massive Open Online Courses (MOOCs) appear particularly relevant in education for sustainability. Teachers need to critically reflect on their teaching to develop as teachers and improve student learning, but the MOOC related literature has paid little attention to teacher development. In this paper, we apply and evaluate a framework for teacher development – Brookfield's critically reflective practitioner – in a MOOC context. We present a case study of two teachers who developed and delivered the *Sustainability in Everyday Life* MOOC. We analyse how they used Brookfield's four reflective lenses: the autobiographical lens, the student lens, the peer lens, and the scholarship lens. While all four lenses contributed to the reflection process, they were insufficient in a MOOC context. Additional and important reflective lenses include the perspectives of the organisational leadership, the public and media as well as learning analytics. We discuss the implications of those additional lenses in the MOOC context, but they could be relevant for modern higher education in general.
